**Commerce and Business**—In 1919, imports were valued at approximately \$9,600,000 and exports at \$5,000,000 and in 1926 at \$18,990,000 and \$13,684,500 respectively. In 1927, the whole foreign trade was valued at \$31,500,000. In 1927 the total trade with the United States was valued at \$18,750,000 (69.09%). The principal items imported in 1926 were cotton goods (\$8,235,000) and iron and steel (\$1,515,000). The principal exports were sugar (\$3,295,000), abaca (\$3,142,000), coco nut oil (\$2,345,000) and copra (\$1,856,500). In 1913 the Underwood Tariff Act abolished all duties between the United States and the Philippines. In 1926 there were in addition to the Philippine National Bank, seven other domestic banks and four foreign banks and trust companies. Their resources totalled almost \$12,800,000.

**Finance and Revenues**—The national wealth of the Philippines was estimated at 5 495 48 000 pesos in 19 3 Money is on a gold basis the unit being the peso which is stabilized at 50 cents US The parity of the silver peso with the theoretical gold peso (the latter being the unit of value in the Philippine Islands consisting of 12<sup>9</sup>/<sub>16</sub> grams of gold <sup>9</sup>/<sub>16</sub> fine) is maintained by the gold standard fund which must not be less than 15% of the money of the Philippine Islands in circulation and available therefor a percentage to be increased until it equals 25% of the total circulation The standard gold fund balance in 1926 was about 21 700 000 pesos The subsidiary coinage consists of one five ten 20 and 50 centavo pieces (one centavo being equal to US ½ cent) On Dec 31 1927 the bonded indebtedness of the insular provincial and municipal governments was 167 985 000 pesos and the sinking funds were approximately 38 543 000 pesos In 1926 insular taxation amounted to approximately 59 23 000 pesos city of Manila taxation to 4 998 000 provincial taxation to 10 946 000 and municipal taxation to 12 222 000 pesos Customs collections in 1926 were approximately 21 180 000 pesos internal revenue taxes 54 544 000 income tax (19 5) 2 343 000 and real estate tax 14 537 000 pesos The budget estimate in 1927 was income 73 153 100 pesos expenditures 72 918 589 Receipts and expenditures of the Insular Government for 1926 amounted to 83 801 854 and 97 633 642 pesos respectively

**Government and Administration.**—When Spain colonized the Philippines the natives were living under loose but fairly well crystallized forms of government the primary unit of which was called 'barangay'. Society was composed of three classes viz serfs freemen and nobles and distinct rules governed each class. The Spaniards with great acumen organized their government partly on the native structure with a governor general as supreme political chief an *audiencia* or supreme court provincial or district governments and municipal governments. Immediately upon conquest tributes were levied on the natives, who were also given in *encomienda* to the *conquistadores*, officials and favoured

Spain and in the archipelago there were rather different conditions. The Philippine Commission was created by the Philippine Commission Act of 1901, which provided for a civil service which was considerably in advance of that in the United States at that time. Military government ceased on July 4, 1901 (except in certain specified regions where it was maintained until July 4, 1901) at which time Judge Taft became the first and only civil governor of the Philippines.

TINGUIAN WOMAN SEEDING COTTON AND BRUSHING THE THREAD

After his term the title was changed to governor general. The government was made directly dependent on the secretary of War who organized the Bureau of Insular Affairs as his immediate agent. This bureau is still in existence and all Philippine matters that need attention in the United States pass through it. In 1901 the membership of the Philippine Commission was increased to seven by the appointment of three additional members—all Filipinos. Shortly afterward four departments of government were created: viz. interior, commerce and police, finance and justice, and public instruction, each with a member of the Philippine Commission as its secretary. In 1901 and 1902 the organization of provincial and municipal governments continued and by Nov. 10, 1903, 37 provinces had been organized.

On July 1, 1901, Congress enacted a provisional enabling or organic act under which the islands were governed until Aug. 9, 1916, when the Jones Bill was passed. The organic act of 1901 provided for a general election and the creation of a popular legislative chamber, the Philippine assembly, which was to become the lower house of a Philippine legislature, the Philippine Commission to be the upper house. An election of members of the Philippine assembly was held on July 30, 1907. All exclusive legislative power was taken from the Philippine Commission and lodged in the legislature, except for territory inhabited by Moros or other Philippine non-Christians. Two resident commissioners were appointed to the Congress of the United States with power to speak on legislation affecting the Philippines but with no vote. In 1908 the Philippine Commission was increased by one more Filipino member. In Oct. 1913 President Wilson appointed a new commission composed of five Filipinos and four Americans. On Aug. 29, 1916, the Jones Bill created a legislature with a Senate of 24 members and a House of Representatives of 91 members (now 92) all elected by popular suffrage except two senators and nine representatives appointed by the governor general to represent the non-Christian provinces of Nueva Vizcaya, Mountain Province, Agusan, Bukidnon, Cotabato, Davao, Lanao, Sulu, and Zamboanga. By virtue of the Jones Bill there are now six executive departments, each under a secretary who is assisted by an under secretary. All these officials except the secretary of public instruction are Philippine citizens. With the exception of the governor general, vice governor (who is also secretary of public instruction), auditor, deputy auditor, the directors of the Philippine constabulary and of the bureaux of education, agriculture, forestry, science, public works, and the coast and geodetic survey, all the departmental secretaries and directors of bureaux are (1919) Filipinos.

With the consent of Governor General Harrison, a Council of

the president of the Senate, the speaker of the House, and the departmental secretaries was formed to coordinate the administration and policies of the Government. Under the Harrison term this organization was accepted by the Government but under Harrison's successor, William Wood, it ceased to function through the refusal of Wood to become a member. It was reestablished by Governor Wood in 1915 and enlarged to include the speaker of the Senate and of the House, thus making it even more representative than the former Council.

The judiciary consists of a supreme court composed of a chief justice (a Filipino) and eight associate justices (three Filipinos). It is appointed by the president of the United States with the consent of the Senate. A court of first instance for each of the 6 judicial districts, the municipal court of Manila, and justice of the peace courts for each municipality.

There are 48 provinces and sub-provinces (excluding Manila which has the rank of a province) of which 39 are regularly constituted and governed by an elective governor who is the executive and a provincial board composed of two elective members and the provincial treasurer which is the legislative branch of the province. In the specially organized provinces the governors and lieutenant governors are appointive officials. The municipal government consists of a president, vice president, and a municipal council. In 1915 there were 80 municipalities, 88 townships, 13 municipal districts, and 1630 barrios.

**History.**—The Philippine archipelago first became known to Europeans on March 16, 1511, through Ferdinand Magellan (q.v.). But there are authentic Chinese accounts of trading voyages as early as the 10th and 13th centuries, and the contact probably went back much further. A Hindu influence undoubtedly came by way of the Malay peninsula, Java, and other islands nearby, and probably reached back to the early centuries of the Christian era. The Hindus influenced the life of the people intimately. Many Sanskrit words in the languages and dialects of the people of the Philippines and the forms of the letters used at the time of their discovery by the Spaniards indicate this.

The second, third, and fourth Spanish expeditions were those of Garcia Jofre de Lousa, of Alvaro de Saavedra, and of Ruy Lopez de Villalobos. The next expedition that of Miguel Lopez de Legazpi (1564-1629) was despatched like its predecessor from New Spain but it was far more carefully planned. Leaving Puerto de Navidad in New Spain on Nov. 20, 1564, Legazpi reached Cebu in April 1565 where the first permanent settlement was made early in May. But Legazpi, with inadequate forces and resources, meeting prolonged hostility from the Portuguese who swarmed through the region at last (1569) moved his main forces to the island of Panay, hoping thereby to have better protection. In 1571 Legazpi made Manila the administrative centre. Thereafter the conquest of Luzon proceeded rapidly at first principally under Juan de Salcedo, the precocious young grandson of Legazpi. All of the archipelago except the Moro islands of Mindanao, the Sulu archipelago, and Palawan were in fairly peaceful possession of the Spaniards before 1600. In June 1571 the city of Manila was formally established. In 1574 Manila was attacked by the Chinese Limahong but he was forced to retire from the island and from the entire group. Several of the provisional governors were churchmen who played into the hands of the ecclesiastics or catered to their own order.

The Spaniards were accepted easily even hospitably in many cases and those coming into closest contact with them began almost immediately to take on the veneer of a superior culture. The conquest was especially easy along the coast and in the low interiors where the Spaniards first went. The principal opposition at Manila in 1570 came from Mohammedans. But that faith was not yet strongly entrenched in Luzon. It was quite different in Mindanao and at various other points in the south. The Spaniards were instinctive enemies of these people for they had had a seven-century fight in Spain against Mohammedanism. To them the word Moro meant Mohammedan or Moor. Accordingly they dubbed the Malayan Mohammedans *Moros* and by this name they are still known. In 1574 the Moros of the Rio

Guaido de Mindaao entered submission in 1571. In 1571 the Spanish conducted a fairly successful expedition against the Moros but the Spaniards were unable to gain any real advantage. Until 1573 piracy had been the main occupation. The Moros ravaged the coast and made even the sea around Manila unsafe. The Moros joined often with the Dutch in the latter half of the 17th century in the oriental waters. In 1571 on Balangir in the island Governor Narciso Claveria y Zedillo won the most decisive victory ever aimed over the Moros. In 1580 Governor Antonio de Urbina y Eguia destroyed the strongholds on Torkil island and the next year stormed and captured the town of Jolo. This ended the real power of the Moros.

SALT WORKS AT MALABON

During the interim between Magellan's discovery and the settlement of Manila the Portuguese actively contested Spanish right to the archipelago. Their hostility ceased only with the union of Spain and Portugal (1580-1640). In 1577, Sir Francis Drake started on the voyage which brought him to the Philippines at Mindanao. Again in 1587, Thomas Cavendish sailed to the Moluccas and thence back to California to intercept the rich galleon Santa Ana. He then went to the Philippines where he tried in vain to capture the shipyard at Iloilo.

The Dutch came next. Their primary object was trade rather than colonies. In 1596-97 Admiral Houtman opened trade with Holland and during the years 1598-1600 the expedition under Neck and Warvick traded in the Moluccas. In 1600 Oliver van Noordt reached Philippine waters where he committed various depredations. Dutch vessels now traded for spices and other oriental wares in the Moluccas, harried the coasts and waters of the Philippines and attacked Portuguese, Spanish, Japanese and Chinese shipping. In 1610 Governor Juan de Silva defeated and killed the Dutch admiral Francis de Wittert at Playa Honda near Manila and captured part of his fleet. In 1640 the Dutch captured Malacca and in 1661 they permanently occupied the Moluccas. Their attacks in the Philippines gradually ceased.

With Legazpi had come five Augustinians in 1577 came the Franciscans in 1580 the Jesuits in 1587 the Dominicans and 1603 the Augustinian Recollects. It was the intention of Spain to replace the friars by secular parish priests whenever any mission assumed the character of a parish. But the friars desirous of retaining their holdings and power fought secularization and it was never carried out in its entirety. The friars became the storm centre of the gradually increasing Filipino demand for change. The insurrection of 1896 was directed principally against them and during the later insurrection against the United States they suffered many indignities.

In 1762 a British expedition reached Manila on Sept. 22 found the Spanish but ill prepared and on Oct. 5 captured the city. By the Treaty of Paris in 1763 Manila was restored to Spain.

The last Manila galleon left the Philippines in 1811 and returned in 1815. Thereupon the trade was taken over by private persons; exports to the value of 750,000 pesos were allowed and three other ports besides Acapulco were opened to it, namely San Blas, Guayaquil and Callao. In 1766 however the crown had allowed direct trade between Spain and Manila by one national vessel annually. In 1785 the Royal Company of the Philippines began to trade between Manila and Cadiz; the company ceased to exist in 1830.

In 1809 an English commercial house was permitted to establish itself in Manila and in 1814 a like privilege was extended to all foreigners but as a rule Spaniards were still jealous of foreigners and reactionary decrees in 1828 and 1840 forbade them to sell goods at retail or to do any business in the provinces. The vacillating Spanish policy is seen again in the opening of seven ports to foreign trade in 1830 and their closing the next year. In 1837 Manila was reopened to foreign trade. Iloilo and Cebu in 1855 and 1863. In 1842 there were 39 Spanish shipping and commercial concerns in Manila and about a dozen foreign

houses. Various governments maintained consuls among them. The British and the United States.

During the first half of the 19th century there were only 100,000 Spaniards in the Philippines. Spanish was spoken by one of the native population in Manila and a few other important centres. The Spaniards made comparatively little effort to educate the natives. There was no homogeneous organization of the native people, very largely because of the caste system. Political conditions in the Philippines represented in the Spanish Cortes carried little meaning or a mistaken one to the mind of the population. After the building of the 'Suez canal' in 1869 ambitious Filipino youths went to Spain and other countries for study. The first daily newspaper, *La Esparanza* (1841), *La Solidaridad* was founded in 1888 in Barcelona by Graciano Lopez Jaena in the interest of Filipino propaganda. It continued its course urged reforms both in religion and government. One of its foremost contributors was the precocious Chinese mestizo Jose Rizal y Mercado. The Filipinos had had ample grounds for complaint especially since 1871. That year some 100 native soldiers at the Cavite arsenal revolted, killed their officers and shouted for independence. Plans for a similar demonstration in Manila failed. The insurrection was quickly suppressed and led to wholesale arrests, life imprisonment and the execution among others of three Filipino secular priests whose connection with the uprising has never been satisfactorily explained.

Meanwhile the gradually expanding idea of Filipino nationality began to manifest itself. The campaign of Rizal, Marcelo del Pilar, Lopez Jaena and Apolinario Mabini, leaders in the Young Filipino Party, was a protest against both the domination of the friars and economic and administrative caciquism. These aspirations met a sympathetic reception from several governors. But other Spaniards, especially the friars, were diametrically opposed and much of the old easy and cordial intercourse between the two peoples was changed. Rizal threw himself into the propaganda with eagerness. In 1891 he founded at Hong Kong an organization called the Liga Filipina and in 1892 formed a branch at Manila. He was arrested in 1896 at Barcelona, returned to the Philippines given a farcical trial and executed on Dec. 30, 1896. At about the time of Rizal's establishment of the Liga Filipina there was also founded an organization called Supreme Worshipful Association of the Sons of the People, which is generally called the *Katipunan*. The organization was altogether Tagalog and is said to have numbered anywhere from 100,000 to 400,000 members. On Aug. 6, 1896 the actual insurrection broke out. The cry of Balintawak is the name given to the first hostilities by the Filipinos. The centre of the revolt was at Cavite where Emilio Aguinaldo first came into prominence. Spain sent over reinforcements until there was an army of 28,000 besides a few loyal regiments of native soldiers. A stiff campaign of 52 days brought the defeat of the insurgents but upon the execution of Rizal the insurrection broke out again and spread to the provinces of Pangasinan, Zambales and Ilocos.

A PHILIPPINE POTTER AT WORK

Spain and the United States. (See SPANISH AMERICAN WAR.) The Filipinos who had declared their independence of Spain on June 12, 1898 proclaimed a provisional republic with Aguinaldo as president and on Sept. 9, 1898 made their capital at Malolos with Apolinario Mabini, the mouthpiece of the revolution, as Aguinaldo's chief adviser. On Sept. 15 a revolutionary assembly met and on the 29th ratified Filipino independence. In November and December revolutionary tribunals were organized in the Bisayas.

During the last few years the islands have suffered considerably from destructive typhoons. Health conditions, on the other

Philip, Katharine (1366-1404) French noblewoman, daughter of John the Fearless and Joan of Burgundy. She was married to Philip the Bold, Duke of Burgundy.

**PHILIPS, KATHARINE** (1366-1404) French noblewoman, daughter of John the Fearless and Joan of Burgundy. She was married to Philip the Bold, Duke of Burgundy. Her husband, Andrew, Sir Charles, Count of Flanders, was a member of the Order of the Golden Fleece. She died of smallpox on June 1664. The literary atmosphere of her circle is preserved in the excellent *Lettres of Orléans to Philippe* published by Bernard Lintot in 1703 and 1709.

See E. W. Goss, *Seventeenth Century Studies* (1883) *Poems by the Incomparable Mrs. K. P.* appeared surreptitiously in 1664 and an authentic edition in 1866. *Selected Poems* edited with an appreciation by Miss L. I. Guiney appeared in 1904. The best modern edition is in Saintsbury's *Minor Poets of the Caroline Period* (vol. 1, 1903).

**PHILIP THE BOLD** (1334-1404) duke of Burgundy, fourth son of John II of France and Bonne of Luxembourg. He was born on Jan. 15, 1334. He earned his surname by his bravery on the field of Poitiers. He accompanied King John into captivity in England. In 1360 he received the title of duke of Touraine and in June 1363 was entrusted with the government of Burgundy which John had united to the crown at the death of the last duke of the Capetian family. Philip of Rouvre in 1361. In September 1363 John made Philip duke of Burgundy and first peer of France. The donation was ratified at the accession of Charles V of France. He took possession of the duchy at the end of 1364. Charles appointed him (in 1366) his lieutenant in Champagne and married him in 1369 to Margaret, daughter and heiress of Louis of Male, count of Flanders and widow of Philip of Rouvre.

Philip proved a faithful ally to Charles. He took part in the almost bloodless campaign against the duke of Lancaster who had landed at Calais. In 1377 he took several towns in French Flanders from the English and in 1379 relieved Troyes which had been besieged by the English. On Charles's death Philip found himself with his brothers the dukes of Anjou and Berry in charge of the government of France in the name of Charles VI who was a minor and in the absence of the duke of Anjou who left France in 1380 to conquer the kingdom of Naples. Philip occupied the most powerful position in the realm. He persuaded the young king to intervene in Flanders where the citizens of Ghent whose rebellious spirit had necessitated Philip's intervention in 1379 had again revolted under Philip van Artevelde and had expelled Louis of Male. On Nov. 7, 1382 the Franco-Burgundian chivalry crushed the rebels at Rosebecke and on his return the duke of Burgundy took part in repressing the popular movements which had broken out in Paris and other French towns. In 1383 an insurrection in Flanders supported by England gave rise to another French expedition but in January 1384 the death of Louis of Male made Philip master of the countships of Flanders, Artois, Rethel and Nevers and in the following year the citizens of Ghent decided to submit. At this period Philip sought to ingratiate himself with the emperor by giving two of his daughters in marriage to two princes of the house of Bavaria. He also took an important part in bringing about the marriage of a princess of the same family Isabel to King Charles VI.

Hostilities however were renewed between France and England. A formidable expedition was prepared under the direction of the duke of Burgundy and a fleet of 1400 sail assembled at Sluys but the enterprise failed owing to the dilatoriness of the duke of Berry. The fatiguing and inglorious expedition in the Netherlands weakened Philip's credit with his nephew who on his return declared himself of age and confided the government to the ancient councillors of his father the Marmousets. The king's madness (1392) restored his uncles to power and particularly Philip who after assuring peace by treating with the duke of Brittany and by concluding a truce of twenty-eight years with

Edward III of England efforts to put an end to the Great Schism. He was elected Benedict XIII at Avignon in 1395 in the place of the voluntary resignation from him. For the duration of the schism he was crowned Charles VI. For a brief period Philip possessed of authority but he regained it in 1401 and died on April 7, 1404. The cathedral of St. Etienne in Dijon contains his remains and his tomb (formerly in the Hotel de ville). Philip governed his territories with sagacity and a certain moderation. He granted numerous privileges to the inhabitants of Dijon and created in 1386 two *chambres des comptes* one at Dijon and the other at Lille. He was in the phrase of a contemporary "kindly and amiable to his high and low and those of noble rank liberal as an Alexander noble and pontifical in court and state magnificent." (R. P. X.)

**PHILIP THE GOOD** (1396-1467) duke of Burgundy son of John the Fearless duke of Burgundy and Margaret of Bavaria. He was born at Dijon on June 15, 1396 and succeeded his father on Sept. 10, 1419. The assassination of John the Fearless (qv) drove his successor to the English side. In 1419 Philip signed with Henry V of England the treaty of Arras by which he recognized Henry a regent and future heir of the kingdom of France and in 1420 gave his adherence to the treaty of Troyes. Early in December 1420 Philip entered Paris with the king of England and subsequently took part in the defeat of the French at Mons en Vimeu. By a treaty concluded by Philip at Amiens in April 1424 with the dukes of Brittany and Bedford John duke of Bedford married Philip's sister Anne and Arthur of Brittany earl of Richmond became the husband of Philip's sister Margaret. A few years later discord arose among the allies. When the duke of Bedford besieged Orleans the inhabitants offered to surrender but to the duke of Burgundy whereupon Bedford retorted that he did not beat the bushes for others to take the birds. When this speech reached Philip's ears he withdrew his troops in dudgeon and concluded a truce with France (1429). Bedford succeeded in conciliating him and in 1430 Philip took part in the campaign against Compiègne.

But another conflict arose between the duke of Burgundy and the English. Jacqueline, countess of Hainaut (see JACOBA) the divorced wife of the duke of Brabant and the heiress of Holland and Zeeland had married the duke of Gloucester who attempted to take forcible possession of his wife's territories. Philip claimed Brabant as a bequest from his cousin Philip the late duke with the result that the Burgundians repulsed the troops of the duke of Gloucester and Jacqueline was forced to recognize the duke of Burgundy as her lieutenant and heir. More over the duchess of Bedford had died in 1433. Charles VII who in spite of the efforts of the cardinal of Ste Croix had hitherto refused to return to France finally decided to take part in the conferences which were opened at St. Vaast d'Arras on Aug. 6, 1435. Philip agreed to recognize the king of France as his legitimate sovereign on condition that he should not be required to pay him homage during his lifetime. Charles solemnly craved pardon for the murder of John the Fearless and handed over to the duke the counties of Macon, Auxerre, Bar-sur-Seine and Ponthieu and the towns on and near the Somme (Roye, Montdidier, Peronne) reserving the option of redeeming the Somme towns for 400,000 gold crowns. Philip faithfully served the king aiding him in re-entering Paris and preparing an expedition against Calais which however failed through the ill will of his Flemish subjects (1436). In 1440 he paid the ransom of Charles of Orleans and married him to Mary of Cleves. In 1442 Philip conspired to give the duke of Orleans a larger share in the affairs of the kingdom.

Philip was frequently disturbed by the insubordination of the Flemish communes. He had to quell seditions at Liege (1430), Ghent (1432 and 1448), Antwerp (1435) and Bruges (1438). Shortly after the final defeat of the citizens of Ghent at Gavre (1453) Philip vowed that he would lead a crusade against the Turks who had seized Constantinople. The expedition however did not take place and was but a pretext for levying subsidies. In 1459 Philip sent an embassy under the duke of Cleves into Italy to

**Traditions of the Philistines.**—The Philistines were prominent in popular tradition and the story of Isaac and the Philistine Abimelech (Gen xxvi, cf xxi. 32) is of great interest for its unbiased picture of enmity alliance and covenant. **PHILISTUS**, Greek historian of Sicily was born at Syracuse about the beginning of the Peloponnesian War (43 B.C.) He was a faithful supporter of the elder Dionysius and commander of the citadel. In 386 he was banished for secretly marrying the tyrant's niece. He commanded the fleet against Dion but was defeated and put to death (356). He settled at Thurii but afterwards removed to Adria where he remained until the death of Dionysius (366). He was then recalled by the younger Dionysius whom he persuaded to dismiss Plato and Dion. During his stay at Adria Philistus occupied himself with the composition of his *Σικελικά* a history of Sicily in eleven books down to 363 from which point the work was carried on by Athanas. Cicero (*ad Q. Fr.* II. 13) calls him the miniature Thucydides (*pusillus Thucydides*).

 Duke of Devon and several of his other works

**PHILLIPS, EDWARD** (1630-1696) En hsn author son o Edward Phillips of the crown office in chancery and his wife Anne only sister o John Milton the poet was born in Aug 1630 in the Strand London His father died in 1631 and Anne Phillips eventually married her husband's successor in the crown office Thomas Agar Edw id Phillips and his younger brother John were educated by Milton Edward entered Magdalen Hall Oxford in November 1650 but left the university in 1651 to be a bookseller clerk in London He was tutor to the son of John Evelyn 1663 to 1667 and in 1667-9 in the family of Henry Barnet earl of Arlington The date of his death is unknown but his last book is dated 1696

His most important work is *Theatrum poetarum* (1655) a list of the chief poets of all ages and countries but principally of the English poets with short critical notes and a prelatory *Discourse of the Poets and Poetry* which has usually been traced to Milton's hand. He also wrote *A New World in Words or a General Dictionary* (1658) which went through many editions a new edition of Baker's *Chronicle* of which the section on the period from 1650 to 1658 was written by himself from the royalist standpoint a supplement (1676) to John Speed *Theatre of Great Britain* and in 1684 *Enchiridion in uae latinae* said to have been taken chiefly from notes prepared by Milton. Aubrey states that all Milton's papers came into Phillips's hands and in 1694 he published a translation of his *Letters of State* with a valuable memoir.

His brother JOHN PHILLIPS (1631-1706) in 1652 published a Latin reply to the anonymous attack on Milton entitled *Pro Rege et populo anglicano*. He appears to have acted as unofficial secretary to Milton but he published in 1655 a bitter attack on Puritanism entitled a *Salve against Hypocrites*. In 1656 he was summoned before the privy council for his share in a book of licentious poems *Sportive Wit* which was suppressed by the authorities but almost immediately replaced by a similar collection *Wit and Drollery*.

An extended but by no means friendly account of the brothers is given by Wood *Aiken oxon* (ed Bliss iv 764 seq) where a long list of their works is dealt with This formed the basis of William Godwin's *Lives of Edward and John Phillips* (1815) with which is reprinted Edward Phillips's *Life of John Milton*

**PHILLIPS, STEPHEN** (1868-1915) British poet and dramatist was born on July 28 1868 at Somertown near Oxford the son of the Rev Stephen Phillips precentor of Peterborough cathedral. He was educated at Stratford and Peterborough grammar schools and entered Queen's college Cambridge but during his first term at Cambridge when F R Benson's dramatic company visited the town he joined it and for six years played various small parts. In 1890 a slender volume of verse was published at Oxford with the title *Primavera* which contained contributions by him and by his cousin Laurence Binyon and others. In 1894 he published *Eremus*, a long poem of loose structure in blank verse of a philosophical complexion. *Poems* (1897) brought him many readers. George Alexander commissioned Phillips to write him a play the result being *Paolo and Francesca* (1900) produced at the St James's Theatre in 1901. Other dramas in blank verse followed *Herod a Tragedy* (1900) *Ulysses* (1902) *The Son of David* (1904) and *Nero* (1906). In these plays three of which were produced by Beerbohm Tree the poet's avowed aim was to revitalize the method of the Greek drama. *Paolo and Francesca* was the most successful. He died at Deal Kent on Dec 9 1915.

See a notice by Arthur Symons prefixed to the edition (1927) of his last play *Harold* which was first printed in the *Poetry Review* Jan and March 1916 also Sir Sidney Colvin in T. Humphrey Ward's *English Poets* (vol. v 1918).

**PHILLIPS, WENDELL** (1811-1884) American orator and reformer, was born in Boston on Nov 29 1811. His father John Phillips (1770-1823), a man of wealth and influence graduated at Harvard college in 1788, and became town advocate and public prosecutor," and in 1822 first mayor of Boston. Phillips attended the public Latin school, entered Harvard college before he was 16

and graduated in 1831. He graduated at the Harvard law school in 1834 and then returned to the Harvard Boston. He also came under the influence of the anti-slavery movement with singing in the choir of the Boston of William Lloyd Garrison.

Amesbury, he held on Dec. 1835 at Faneuil Hall to express the opinion of the people on the murder of Elijah P. Lovejoy at (III) for doing his presidential proslavery mood. In the 1840s the meeting place was made in opposition to a general tour of James T. Ausin as a general of the State who said that Lovejoy had died a the fool die and compared his murder to the one who threw the tea into Boston harbour just before the War of Independence. The speech seemed likely to offend the audience when Wendell Phillips took the platform.

When I heard he said the gentleman lay down principles which placed the murderers of Alton side by side with Otis and Hancock with Quincy and Adams. I thought the depicted lips (pointing to their portrait) would have broken into voice to call the recreant American the slanderer of the dead. This appeal not merely determined the sentiment of the meeting it gave Wendell Phillips his first fame and determined his career.

Although loving his profession and this especially for the opinion it gave in the direction of public life he lived henceforth the life of an agitator or like his father that of a public prosecutor. Accepting unhesitatingly the leadership of Garrison and becoming like him a disunionist he lived essentially a platform life interested in a variety of subjects but first and chiefly an abolitionist. In 1863 however after the Civil War he broke with Garrison over the question of discontinuing the Anti Slavery Society and from that date until the society was disbanded in 1880 he instead of Garrison was its president. Phillips style of eloquence was direct and brilliant but eminently self controlled. He may be said to have introduced the direct and colloquial manner upon the American public platform. His logic while never obtruded was rarely at fault but he loved the flash of the rapier and was never happier than when he had to face a mob and utterly foil it by sheer superiority in fencing. The two volumes of his speeches as edited by James Redpath were fortunately made from verbatim reports and they wisely enclose in parentheses those indications of favour or dissent from the audience which transformed so many of his speeches into exhibitions of gladiatorial skill. After slavery had fallen Phillips associated himself freely with reformers occupied in other paths. He contended in later years for prohibition woman suffrage and various penal and administrative reforms. He died in Boston on Feb. 2 1884.

See his *Speeches, Lectures and Letters* (1892) Lorenzo Sears *Wendell Phillips Orator and Agitator* (1909) also George L. Austin *The Life and Times of Wendell Phillips* (1888) C. E. Russell *Story of Wendell Phillips Soldier of the Common Good* (1914) and George Edward Woodbury *Heart of Man and Other Papers* (1920).

**PHILLIPSBURG**, a town of Warren county New Jersey USA on the Delaware river opposite Easton Pa. served by the Central of New Jersey the Lackawanna the Lehigh and Hudson River the Lehigh Valley and the Pennsylvania railways. Pop. (1900) 1693 and 19255 in 1930. The city rises from the river bottom to bluffs commanding fine views. It has railroad shops and various other manufacturing industries making mining and agricultural machinery silk and many other products. The aggregate output in 1927 was valued at \$28,492,312. Phillipsburg was settled about 1750 but it was only a straggling village until the Morris canal was constructed (1825). An iron furnace was established in 1848 and the Central railroad of New Jersey reached the town in 1851. It was incorporated in 1861.

**PHILLIPSITE**, a mineral of the zeolite group a hydrated potassium calcium and aluminum silicate approximating to  $(K, Ca)Al_2(SiO_3)_4 \cdot 4H_2O$ . It varies somewhat in composition and a variety ('pseudophillipsite') containing rather less silica has the formula  $(K, Ca)_2Al_2Si_4O_{13} \cdot 9H_2O$ . Crystals are monoclinic but only complex cruciform twins are known these being exactly like twins of harmotome (*qv*) though the phillipsite crystals are usually smaller and more transparent and glassy. Spherical groups with a radially fibrous structure and bristled with crystals on the surface are not uncommon. The hardness is 4½ and the specific gravity 2.4. The species was named in 1825 after William Phillips;

French mineralogists call it christianite (after Christian VIII of Denmark).

Phillipsite is a mineral of secondary origin and occurs with other zeolites in the amygdaloidal cavities of basic volcanic rocks in the basalt of the Grimsby and Co. Arcturum and near Melbourne Victoria and in the tuff near Rome while small crystals of reccer formation occur in the masonry of the hot baths at Pont-à-Mousson and Bourbomne in France. Minute pherical aggregates embedded in red clay were dredged by the Challenger from the bottom of the central Pacific where they had been formed by the decomposition of volcanic ash.

**PHILLPOTTS, EDEN** (1806 - ) British novelist poet and dramatist was born in India on Nov. 4 1806 and educated at Plymouth. He was a clerk for ten years in the Sun fire insurance office then studied for the stage but turned his attention to literature producing a number of successful novels with a Devonshire setting.

**PHILLPOTTS, HENRY** (1778-1869) English bishop was born at Bridgwater on May 6 1778 and was educated at Gloucester College school and at Corpus Christi college Oxford. He became a fellow of Magdalen college Oxford in 1795 took orders in 1800 and was select university preacher in 1804. For twenty years he was chaplain to Shute Barrington bishop of Durham. He held in succession important preferments and was consecrated bishop of Exeter in 1831 holding with the see a residentiary canonry at Durham. In 1819 he had defended the existing poor law and the action of the Government in the Peterloo massacre. In 1825 he vehemently opposed Catholic emancipation engaging in a fierce polemic on the subject with Charles Butler (1750-1832). He continued to support the Tory party even when it passed the Roman Catholic Emancipation Act of 1829. He died on Sept. 18 1869. Henry of Exeter as he was commonly called had little sympathy with either Evangelicals or Tractarians. The famous Gorham judgment was the outcome of his refusal to institute to the living of Bramford Speke a clergyman George Cornelius Gorham (1787-1851) who had openly disavowed his belief in baptismal regeneration he denounced the equally famous Tract 90 in his episcopal charge of 1843.

See R. N. Shutte *The Life of Dr. Phillpotts* (1863).

**PHILO**, often called **PHILO JUDAEUS** Jewish philosopher appears to have spent his whole life at Alexandria where he was probably born c. 20-10 B.C. His father Alexander was alabarch or arabarch (that is probably chief farmer of taxes on the Arabic side of the Nile) from which it may be concluded that the family was influential and wealthy (Jos. *Ant.* xviii. 8. 1). The only event of his life which can be actually dated belongs to A.D. 40 when Philo then a man of advanced years went from Alexandria to Rome to persuade the emperor Gaius to abstain from claiming Divine honour of the Jews. Of this embassy Philo has left a full account (*De legatione ad Gaium*).

**The Hellenistic Jew.**—Philo is the most important representative of Hellenistic Judaism and his writings give us the clearest view of what this development of Judaism in the diaspora was and aimed at.

Philo appears to have been the greatest of all the Jewish philosophers of the Alexandrian school. On one side he is quite a Greek on the other quite a Jew. His language is formed on the best classical models especially Plato. He knows and often cites the great Greek poets but his chief studies had been in Greek philosophy. His system was eclectic but the borrowed elements are combined into a new unity with so much originality that he may fairly be regarded as representing a philosophy of his own which has for its characteristic feature the constant prominence of a fundamental religious idea. Philo's closest affinities are with Plato the later Pythagoreans and the Stoics. Yet with all this Philo remained a Jew, and a great part of his writings is expressly directed to recommend Judaism to the respect and if possible the acceptance of the Greeks. He was not a stranger to the specifically Jewish culture that prevailed in Palestine. In Hebrew he was not proficient, but he had evidently made some study of that language. His method of exegesis is identical in form with that of the Palestinian scribes, and there are coincidences in matter. Philo recog-

himself. Micra h The m m d e r i that the char ers whel

IV Besides the above named three great works on the Penta  
 tuch Philo was the author of a number of isolated writings of  
 which the following have reached us either in their entirety or in  
 fragments (1) Περὶ βίου Μωσέως (Vita Moysis lib 1—III M II  
 80—119) (2) Περὶ τοῦ πάντα σπουδαίων εἶναι ἐλευθερὸν (Quod  
 omnis probus liber M II 445—410) The genuineness of the writ  
 ing now possessed by us is not undisputed but see Lucius Der  
 Essensismus (1881) pp 15—3 (3) Εἰς Φλάκκον (Adversus Flac  
 cum M II 511—544) and (4) Περὶ ἀρετῶν καὶ πρεσβείας πρὸς  
 Γαίον (De lectione ad Gaium M II 545—600) These two works  
 have a very intimate connection. In the first Philo relates how the  
 Roman governor Flaccus in Alexandria towards the beginning of  
 the reign of Caligula allowed the Alexandrian mob to persecute the  
 Jews. In the second he relates the persecution under Caligula that  
 divine honours should be everywhere accorded to him and how  
 the Jews of Alexandria in vain sought relief by a mission to Rome  
 which was headed by Philo. These were parts of a larger work in  
 five books (5) Περὶ προνοίας (De providentia) This work has  
 reached us only in an Armenian translation which has been edited  
 with a Latin translation by Aucher (see below) 182 It is men  
 tioned by its Greek title in Eusebius (H E II 18 6 Praep Ev VII  
 10 fin VIII 13 fin ed Gaisford) (6) Ἀλεξάνδρου ἡ περὶ τοῦ λόγον  
 εἶναι τὰ ἀλογα ζῶα (De Alexandro et quod propriam rationem muta  
 animalia habeant so Jerome De Vir Ill c 11) the Greek title  
 is given in Euseb H E II 18 6 This also now exists only in an  
 Armenian translation which has been edited by Aucher Two  
 small Greek fragments occur in the Florilegium of Leontius and  
 Johannes (Mai Scr vet nov coll VII 1 pp 99 100a) (7)  
 Τραπεζικά, a writing now known to us only through fragments  
 preserved in Euseb Praep Ev VIII 6 7 (8) Περὶ Ἰουδαίων a  
 title met with in Euseb H E II 18 6 The writing is no doubt the  
 same as Ἡ ὑπὲρ Ἰουδαίων ἀπολογία from which a quotation is  
 given in Euseb Praep Ev VIII 11 To this place also perhaps  
 belongs the De nobilitate (M II 437—444) which treats of that  
 true noblesse of wisdom which the Jewish people does not lack

V The doubtful treatises (1) Περὶ βίου θεωρητικῶν ἢ ἱερῶν  
 ἀπερῶν (De vita contemplativa) the sole original account of an  
 ascetic community known as the Therapeutae (q v) having their  
 home on the shores of Lake Mareotis (2) Περὶ ἀφθαρσίας κόσμου  
 (De incorruptibilitate mundi) declared unauthentic by Z Frankel  
 and J Bernays has been defended by F Cumont (3) Περὶ  
 κόσμου (De mundo) It is generally agreed that in L Cohn's

word this is nothing but a compilation from various portions of  
 the ἐπεὶ ἀσφαρίας κόσμου and the Philonic works (4) Two  
 discourses D's m f o n e and D's I n e x t a n o n l y i n A r m e n i a n

**PHILOCTETES**, son of Poeas king of the Mahans of Mt  
 Oeta a celebrated hero of the Trojan War. Homer merely states  
 that he was distinguished for his prowess with the bow that he  
 was bitten by a snake on the journey to Troy and left behind in  
 the island of Lemnos and that he subsequently returned home in  
 safety. In the post Homeric accounts Philoctetes or his father  
 had been given the bow and arrows of Heracles (see HERCULES)  
 as a reward for kindling the fire on Mt Oeta on which the hero  
 immolated himself. Philoctetes remained at Lemnos till the  
 tenth year of the war. An oracle having declared that Troy could  
 not be taken without the arrows of Heracles Odysseus and  
 Diomedes (or Neoptolemus) were sent to fetch Philoctetes. On  
 his arrival before Troy he was healed of his wound by Machaon  
 and slew Paris shortly afterwards the city was taken. On his  
 return to his own country finding that a revolt had broken out  
 against him he again took ship and sailed for Italy where he  
 founded Petulia and Cremona. He fell fighting on the side of a  
 band of Rhodian colonists against some later immigrants from  
 Pallene in Achaea. His tomb and sanctuary were shown at  
 Macalla on the coast of Bruttium.

**PHILODEMUS**, Epicurean philosopher and poet was born  
 at Gadara in Coele Syria early in the 1st century B C and settled  
 in Rome in the time of Cicero. He was a friend of Calpurnius  
 Piso and was implicated in his profligacy by Cicero (in Pisonem  
 29) who however praises him warmly for his philosophic views  
 and for the elegans lascivia of his poems (cf Horace Satires  
 I 120). The Greek anthology contains thirty four of his epi  
 grams. Thirty six treatises attributed to Philodemus were re  
 covered from a villa at Herculaneum.

The Rhetoric has been edited by Sudhaus (1892—95) the De  
 Ira and the De Pietate by Gomperz (1864—65) the De Musica by  
 Kempke (1884) De Virtus by Ussing (1868) De Morie by Mekler  
 (1886) See Herculi Volum (Oxford 1824 and 1861) Mayor on

 der Philosophie Bd I (1926)

**PHILOLAUS** (b c 480) Greek philosopher of the Pytha  
 gorean school born at Tarentum or at Crotona (so Diog  
 Laert VIII 84) was probably a teacher of Democritus. After the  
 death of Pythagoras great dissensions prevailed in the cities of  
 lower Italy. According to some accounts Philolaus obliged to  
 flee took refuge first in Lucania and then at Thebes where he  
 had as pupils Summius and Cebes who subsequently being still  
 young men were present at the death of Socrates. Before this  
 Philolaus had returned to Italy where he was the teacher of

The most important discovery of that period was the palatal law ' by which certain consonantal peculiarities were used to prove that Sanskrit in prehistoric times had had a vocalic system similar to that of Greek with *e* and *a* in definite cases where Sanskrit as we know it has uniformly *ā*. The belief in the absolute primitivity of Sanskrit, which had been a dogma in the

**Language and Racial Psychology.**—While most of those who have dealt with the general problems of the nature of language and its development have started as was natural from the European languages and the great family of languages to which they belong there have been other scholars whose endeavours have been especially directed towards the understanding of the psychology of language and who have therefore to a great extent gone outside the languages spoken by civilized nations to ascertain relations between the language of a race and its culture and mental characteristics. A pioneer in that direction was Wilhelm v Humboldt whose great work on the Kawi language was prefaced by a profound investigation into the differences in structure of the various human languages and their influence on the mental development of man (1836-40). His chief disciple was H. Steinthal who in numerous works treated of the relation between language logic and psychology. His best work *Charakteristik der hauptsächlichsten Typen des Sprachbaues* (1860) was completely remodelled in 1893 by F. Mistlisch and in this shape is still a most useful survey of the grammatical structure of

The more certain dating of Philoponus' collection of commentaries on Aristotle's works include the work on the *Physics*, the *Prior* and the *Metaphysics*. It is also possible that the *De generatione et corruptione*, the *De sensu et sensibilibus* and the *Metaphysica*. He wrote in track on Proclus and probably two treatise on mathematics. *Commentary on the Mathematics of Nicomachus* edited by H. Heide (1954 and 1956) and a *Treatise on the Use of the Astrolabe* published by Heide. This is the most ancient work on this instrument.

**PHILOSOPHY, HISTORY OF** An adequate account of the history of philosophy would have to include not only the history of ethics logic psychology metaphysics etc but also an account of the early history of science For obvious reasons such a thing cannot be attempted here Moreover the histories of ethics logic and psychology have separate articles devoted to them and the articles on aesthetics and theory of knowledge also contain the essentials of their history As there are also separate articles dealing with the chief schools of philosophy and with the leading philosophers the present article will only attempt to be a general guide to the study of the history of philosophy

To write of ancient philosophy is essentially Greek philosophy. The modern day re-valuation of European philosophy is in many ways even Greek philosophy considered in the Eastern modes in India or Asia Minor and that was its proper sphere of influence. Philosophy entered the province of Greece as a significant and Greek radiations prior to the influence of Egypt on teacher upon Thales Pythagoras. Descartes and other Greek thinkers. Moreover India China and Persia as well as Egypt are known to have developed more or less independent world view of their own. Students of oriental thought can trace certain counterparts of all or nearly all the main tendencies of Western philosophy—Monism and Dualism Materialism and Idealism Atheism and Pantheism Pragmatism and what not. One may even point to certain direct oriental influences on Western philosophy in the case of Neo Platonism in ancient times in the case of Arabian or Moslem influences in the middle age and in the acknowledged influence of Buddhism on modern philosophy as Schopenhauer. But it remains true that Western philosophy from Thales onwards is sufficiently self contained to warrant separate treatment. And when the ground to be covered is enormous and difficult it is a great convenience to be able to deal with the main stream of philosophy by itself. But there are separate articles dealing with Brahmanism Buddhism Indian philosophy Arabian philosophy Jewish philosophy etc. for those readers who wish to go further afield.

**Ionian Philosophers**—A group of Ionian thinkers first raised the question as to the nature of the substance of which all things are composed from which they originate and into which they are dissolved again. Moreover they raised and answered this question in a non-mythological impersonal manner. They considered *what* not *who* had produced all these things. Their answers were always in terms which we may be tempted to describe as *material*. But that would not be quite correct because as yet no hard and fast line was drawn between the mental and the material. The ultimate matter of which they thought was a living matter—they were consequently not materialists but hylozoists. The Ionian group consisted of the following Milesians:

*Thales* (?640-550 B.C.) regarded water or moisture as the primary stuff or principle of things. In the then state of knowledge many physical phenomena must have appeared to bear out this view. For water is found in the form of gaseous vapour and of solids as well as in liquid form. In the phenomena of rising vapour and of sunbeams people saw the sun and other fiery bodies drawing water for their sustenance so that water seemed capable of changing into fire. In the earth's absorption of rain in the formation of deltas in the alluvial deposits left by torrents water appeared to be changed into earth. In the formation of dew and in the rising earth mists earth seemed to change into moisture. And moisture was of course realized to be necessary for all living things. In these various phenomena *Thales* probably thought that he observed examples of the whole cosmic process from water and back into water.

*Anaximander* (?610-545 B C) was impressed by the conflicting character of such natural qualities as hot and cold dry and wet etc and could not believe that water could generate things with qualities opposed to its own. He held that primary matter must be something different from any of the known determinate kinds of matter which have resulted from it. He accordingly identified primary matter with the unlimited by which he probably meant something indeterminate out of which the determinate things earth water air and fire differentiated or separated out. These four kinds according to *Anaximander* arranged themselves in successive layers with earth at the centre followed by rings of water air and fire in turn. The sun moon and stars he regarded as masses of fire flung off by the world's outer ring of fire surrounded partly by husks or envelopes of air similarly flung off by the cosmic ring of air. Eclipses he explained as due to temporary obstructions in the apertures of the air husks of the sun.

*Xenophanes* of Colophon (?570-480 B.C.) the founder of the Eleatic school, is chiefly noteworthy for his very scathing attack on the Homeric, Hesiodic and similar anthropomorphic conceptions of the gods. "Mortals," he remarked, "believe that the gods come into being as they themselves do, that they have senses, voice, body." But if oxen or lions had hands, oxen would make gods like oxen, horses would make gods like horses. He himself believed in one God, altogether different from man. There is one supreme God, like to mortals neither in body nor in thought. In fact, *Xenophanes* was a pantheist, as seems clear

Anaxagoras (?500-428 B.C.) held that originally there was not one kind of primal matter but a multiplicity of all sorts of parts or seeds of things. These were all mixed up in chaotic confusion. But they were sorted out and arranged in an orderly manner by the intelligence or reason which pervades the universe. This reason is omniscient and omnipotent but was still conceived by Anaxagoras in a semi-material fashion. This doctrine of the multiplicity of seeds through new combinations of which new things come into being and by the separation of which they cease to be paved the way for the atomic theory. The conception of 'mind' or 'reason' as introducing order into things was subsequently adapted by Aristotle. Most important per

1. The first that Anaxagoras went to Athens to teach philosophy was a native of Ionia and a pupil of Anaximander.

*Empedocles of Agrigento* (495-430 B.C.) regarded the four elements as the basis of all things. He believed that the universe was composed of four elements: earth, water, air, and fire. These elements were in constant motion and combination, and he believed that the universe was a single, unified whole. He also believed that the elements were the basis of all life, and that the human body was composed of the same four elements. His theory of the four elements was a major contribution to the development of Greek philosophy.

*The Atomists*—The pluralist opposition to the Eleatic conception of reality as a single, immutable One culminated in the atomist theory. This was first formulated by Leucippus (c. 500-450 B.C.) who first insisted on the reality of empty space which he regarded as non-being. But the atomist theory is chiefly associated with the name of his disciple Democritus who is commonly described as the father of physics.

*Democritus* (460-370 B.C.) is the most important Greek exponent of the atomic theory and the mechanistic method of explanation which is intimately associated with it. According to Democritus, atoms and space are the only ultimate realities. The atoms were conceived by him to be of various sizes and shapes. And all the main differences in composite bodies were reduced to differences in the (a) size and shape (b) position and (c) arrangement of the atoms composing them. The atoms may thus be described as the alphabet of the universe and Aristotle actually illustrates these distinctions of Democritus by means of letters of the alphabet. Using Roman instead of Greek letters the above distinctions may be illustrated as follows: (a) The letters A and M are different in size and shape (b) the letters M and W are different in respect of position (c) The syllables AM and MA are different in respect of arrangement. The last distinction (c) is clearly reminiscent of the Figure or Form of the Pythagoreans. It is especially worth noting that the Atomists held that the atoms are naturally endowed with motion and so avoided the problem which perplexed all subsequent ages until the time of Newton as to how passive matter was set in motion. The natural mobility of atoms seemed to require a void or empty space for them to move in. Hence the recognition by the Atomists of the existence of space. Now the atoms flitting about in all directions collide, some of them get hooked together and combine in various ways owing to their various shapes, then the larger constellations of them enclose other atoms or smaller clusters of them and so all sorts of things are produced including whole systems or worlds. Under certain conditions the various clusters break up again into separate atoms. The systematic attempt to explain everything in terms of matter and motion necessitated then as subsequently the denial of the ultimate reality of the so-called secondary qualities—colour, sound, taste, smell, etc. So the atomists dismissed them as mere conventions, that is as the effects of human intervention or as merely subjective or illusory appearances. (See DEMOCRITUS)

#### THE GOLDEN AGE OF GREEK PHILOSOPHY

*The Sophists*.—After their victory over the Persians the Greeks experienced something similar to the change of general outlook that was brought about by the great World War 24 centuries later. The desire for the good things of life spread among wider circles of people. And there was an increased desire for knowledge at once as a good thing in itself as a social and political aid and possibly as a means to a new orientation after the shock to traditional beliefs and habits which is generally caused by a great upheaval like a war. The general demand for knowledge naturally produced a supply of popular teachers. And so the Sophists came into being. These 'wise men' or teachers of wisdom rendered valuable services to the cause of general

education. They not only helped to create a wider interest in philosophical and other problems but by their criticisms compelled greater thinkers to probe more deeply into the questions raised. Even a Sophist like Protagoras who then always showed himself to be a relativist, did not deny the value of the Sophists. The people of Athens enjoyed the Sophists' teaching and the Sophists were only long after their death remembered as the teachers of the Sophists. The most famous of the Sophists were Protagoras, Gorgias, Hippas, and Prodicus. Each of the Sophists had his own method of showing how to make the best of every situation. In order to make a public display of their own knowledge in the art of debate, they would have been unable to accept any generally accepted view—anybody might go to it. They could give much better proof of their skill by demonstrating lost causes, paradoxes, views that seemed strange or even absurd at first—they had to make the worse case appear the stronger. Aristophanes complained: The effect of all this was sure to be demoralizing upon some of the young Athenians. And their criticism of existing social and political institutions was no doubt distasteful to some of the propertied and influential people. Hence their unpopularity with some. In the history of philosophy their importance consists mainly in the interest which they roused in ethical problems and in problems of knowledge. The most important doctrine associated with their name is that enunciated by Protagoras in the dictum: Man is the measure of all things. By this he meant that there is no such thing as a universally valid knowledge. Different people have different views and for each person that is true which he honestly and to the best of his ability believes to be true. Similarly with moral goodness. In a world of merely relative standards some of the Sophists maintained it was no good pursuing truth better to adapt oneself to the practical needs of life in the environment in which he finds himself. (See SOPHISTS)

*Socrates* (469-399 B.C.) was counted by his contemporaries among the Sophists. For he too was interested in educating young people by means of discussions (though he taught without pay) he also was interested in problems of human conduct rather than in problems about the ultimate nature of reality and he also did not see absolute truth in the opinions commonly entertained. But unlike the Sophists he did believe in the possibility of knowledge provided it were pursued in the right way. And the way which he proposed is that known subsequently as the Socratic Method (*g v*). This method consisted essentially in checking one's ideas by constant reference to relevant instances until they are transformed into universally valid concepts or ideas. In essence it is an inductive method proceeding by elimination though Socrates applied it to a sphere of problems in which the relevant data could be obtained by merely cross-examining people. Ideas checked and corrected in this way so as to agree with the relevant facts are true and altogether above the merely fluctuating opinions of men based on bare sense perception or tradition or hearsay. So convinced was Socrates of the possibility of real knowledge and so impressed with its importance that he based all else upon it, identifying moral good or virtue with knowledge. By thus identifying virtue with knowledge he may have thought that he also cured morality of the mere relativity which the Sophists had found in it. Yet he was condemned as a corrupter of the young and died as the first known martyr in the cause of philosophy. (See SOCRATES)

*The Successors of Socrates*.—As Socrates had never given formal instruction and moreover left no writings behind him it was easy and natural for different people to have different impressions of his teaching.

*Aristippus and the Cyrenaics* laid stress on the cheerfulness of Socrates and his capacity for reasonable enjoyment when an opportunity presented itself. They taught accordingly a hedonistic ethic with pleasure as the highest good. (See CYRENAICS)

*Antisthenes and the Cynics* on the other hand were impressed chiefly with Socrates' indifference to hardships of every kind, his readiness to go without things when necessary. They accordingly preached the simple life, and *Diogenes* carried it so far as to reduce it almost to the life of a dog. (See CYNICS)

*Euclid and the Megarians* were interested mainly in Socrates

conception of the nature of real knowledge namely that the concepts of perception are disintegrated from real opinions by the operation of the senses. He adopted a rather sceptical attitude toward sense perception and sense objects and developed a connection with this sceptical propaganda a form of disputation or criticism which became notorious for its excessive subtlety. But by far the most important of the informal disciples of Socrates was Plato who to some extent shared the views of the Megarians (See MEGARIC SCHOOL).

**Plato** (427-347 B.C.) first studied philosophy under a follower of Heraclitus. At the age of 20 he came under the influence of Socrates and remained in close touch with him until his death in 399. Plato then travelled for a while in southern Italy where he came into contact with the Pythagoreans. All these influences may be discerned in his philosophy which they helped to shape. When in 387 Plato opened a school (the Academy) in Athens the Pythagorean must have betrayed its presence in the inscription "Let no one who knows no Geometry come under my roof".

Plato's philosophy is one of epistemological and ontological idealism. The way in which he arrived at it may be briefly indicated as follows. He agreed with Heraclitus that all objects of sense perception are in ceaseless flux undergoing incalculable changes. No universal truth can therefore be asserted about this ever rolling stream. On the other hand Plato also agreed with Socrates that real knowledge is possible but only in the form of concepts or universal truths. So he concluded that the objects of real knowledge are not the ever changing things of the sensible world but supra-sensible objects which are immutable and eternal. These supra-sensible eternal immutable objects he called Ideas or Forms. The world of change is not indeed a mere illusion. But it consists of things that have only a lower degree of reality things that are but poor imitations of the corresponding Ideas after which they are named. Plato thus distinguished two principal types of object and two principal types of cognition corresponding to them. Real knowledge (or science or the higher kind of cognition) has Ideas for its objects. Sense perception is but opinion a lower kind of cognition which has the world of change for its objects. Or again knowledge is concerned with the world of (eternal) Being opinion is concerned with the world of mere becoming and passing away.

It is possible that what Plato really meant by his Ideas was the laws of things and events that when he described the ordinary things of the sensible world as copies of the Ideas he simply meant that they conform more or less to those laws and that the copies are poor in the sense that their conformity to law is only approximate not exact. However this may be Plato's conception of the world is that of a real system. But it is a teleological system not a merely mechanical system. He gives expression to this conception by identifying the essence of the universe with the Good. The conception was probably the result of Socratic influence. Socrates had identified the real character or essence of a thing with what it is good for. He had made enemies by his insistence that rulers and generals etc. are not merely people who catch enough votes to be elected to office but people who really know the business of a ruler or of a general etc. who really are good for the end in view. By extending this conception to all things Plato conceived all things as adapted to various ends these ends as subordinated or adapted to higher ends and so on to a final end, the Good which is the purpose or ultimate end of the universe as a whole (See ACADEMY GREEK ETHICS HISTORY OF KNOWLEDGE THEORY OF PSYCHOLOGY HISTORY OF).

Philosophy is an attitude of mind as well as a system of ideas. As an inspirer of the philosophic attitude Plato has never been surpassed and but rarely equalled if at all. Philosophy needs both the ideas and the attitude. Great philosophic ideas indeed, are impossible without the philosophic attitude. But there is a kind of enthusiastic attitude that seems to be possible without ideas. And the teaching of philosophy has often suffered from it.

**Aristotle** (384-322 B.C.) is in some ways the most important thinker in the history of ancient philosophy. It was he who gave to philosophy the articulation which it has retained more or less ever since. His writings (even in the incomplete and

incomplete form in which they have been transmitted to us) contain a contribution and very important contribution to all the main departments of philosophy of most of which he may be regarded as the founder. And he is being the great architect of the whole structure of philosophy and the most comprehensive or the title of a philosopher he also gathers up practically all that was in ancient philosophy.

For Aristotle Aristotle studied in Plato's Academy (367-347) and his own philosophy though different in many ways from that of Plato contains many Platonic elements. Undoubtedly Aristotle was more realistic more empirical than Plato and that will account for most of the other difference between them. But even that primary difference must not be exaggerated.

The general tendency of Plato's philosophy was to divide the universe into two parts the relation between which he did not make clear. On the one hand there was the world of becoming of change of sense enjoying an inferior sort of reality on the other hand the world of being the world of ideas eternal and supremely real and only remotely copied by the inferior world of change. Such at all events was Aristotle's interpretation of Plato and he did not agree with such a disruption of the cosmos. While agreeing with Socrates and with Plato on the importance of ideas in the sense of concepts if there is to be real knowledge he felt that Plato's conception of Ideas and their aloofness from the particular objects of sense perception offered no explanation at all for the relation of copying was a mere metaphor. Yet the primary business of ideas is to explain the world of experience not merely to constitute an additional world.

The fundamental ontological conceptions in the philosophy of Aristotle are those of *Matter* and *Form*. The term *Form* is essentially equivalent to Plato's *Idea* which was itself an offshoot of the Pythagorean *Form*. The early Ionians were only concerned with the problem of primary *matter*. Pythagoras had been so preoccupied with *Form* that he almost forgot matter or regarded *Form* as the primal matter or stuff of all things. Plato had removed the Forms or Ideas from the material world into a heaven of their own. Aristotle endeavoured to get a right conception of both matter and form and of the relation between them. The conclusion at which he arrived was that form is immanent in matter the ideal is immanent in the material the universal is immanent in the particular they are not generally divorced from each other they are distinguishable but not separable. To understand Aristotle's view it is well to remember that he was the greatest biologist of antiquity perhaps of all times. Plato was a geometrician and that before the invention of co-ordinate geometry. His preoccupation was with ideal geometrical figure eternal and static. His Ideas were conceived by his mind after the pattern of these eternal and static figures. Aristotle was a biologist preoccupied with the phenomena of growth and development the transition from the potential to the actual from the seed to the embryo and from the embryo to the fully developed form of animal.

Aristotle accordingly was not perplexed by phenomena of change and did not consider process incompatible with reality. And so he distinguished in all things matter from form the relatively raw stuff from the relatively finished product. He applied the distinction all round not to material things only. The distinction naturally cannot be quite the same in all cases and it is relative in more senses than one. The form of a statue is a shape as distinguished from the marble which constitutes its matter. The form of a human character is a certain organization of the instincts and impulses which constitute the raw material before they have been licked into shape. The form of a plant an animal a man consists of a certain function—nutrition sensibility and reason respectively—which distinguishes it from what is below it in the scale of existence and so on. Again nothing is entirely without form. Even the block of marble has some shape before it becomes a statue impulses and instincts have some sort of co-ordination at every stage in the process of character formation and the things which in virtue of their several highest functions are plants or animals or men would still be something even in the absence of those functions only.

were all very similar. They all reached for a kind of truth which the gods had given them and they interpreted the need of man in one or another way of expression.

*Plotinus* (c. 204-270) and *Proclus* (c. 410-485) of *Platonism*. One of the most important characteristics of *Plotinus* has already been pointed out in the explanation of the predominance of ethics in *Plotinus*. Another characteristic of *Plotinus* is that he had a very marked religious side. The philosophy which had a very marked religious side was that of *Plotinus*. The new movement accordingly was first regarded as a form of *Platonism*. Eventually, however, it was renamed *Neoplatonism*. Of the early *Neoplatonists* the best known is *Philo Judæus* of Alexandria. He was the head of a group of cultured Jews who tried to harmonize Hebrew religion with Greek philosophy. By interpreting the Bible allegorically, *Philo* sought to read *Platonism* into *Hebraism* and *Hebraism* into *Platonism*. But *Neoplatonism* owes its success mainly to *Plotinus* (AD 204-270) and *Proclus* (410-485). This school also may claim a distinguished Roman as one of its adherents, namely the Emperor *Julian the Apostate* (reigned 361-363).

According to *Plotinus* the ultimate source of all things is God of whom it is impossible to predicate anything because He is logically prior to anything that can be predicated. Now God acting on a creative impulse created a Spirit (*vous*) somewhat like Himself. This Spirit acting on a like impulse created another, namely the World Soul. This created other souls and so on until the series of productions in accordance with the law of diminishing spiritual returns ends in that extremely low kind of souls called matter. The process of creation is usually conceived as a kind of emanation analogous to the sun's emission of light, sometimes however creation seems to be reduced to a logical or quasi-logical relationship. The World Soul (the creation of the first Spirit created directly by God) is conceived as a group or system of spirits very like the Platonic Ideas, at once thoughts and objects but perfect and immutable. As the creations or emanations are held to be immanent in the creators, the *Neoplatonist* universe is really one spiritual system, all the parts of which are spiritual though in varying degrees. The human soul has fallen from a higher grade of spirituality and can only regain this by a training in asceticism and mysticism and after a series of successive births. The *Neoplatonism* of *Plotinus* with its system of graded spiritual emanations from God was readily adapted to the then prevalent *Polytheism* and belief in spirits and spectres of all sorts. Greek *paganism* thus received a new lease of life under *Julian the Apostate*. *Plotinus* also criticized the Christian exaggeration of man's place in the universe and of the importance of prayer without work. (See *NEOPLATONISM* PHILO PLOTINUS PROCLUS)

*Cicero* (106-43 BC) and the *Eclectics*. Philosophers who neither construct a system of their own nor embrace an existing system as a whole but adopt and combine parts belonging to different systems are called *eclectics* or *syncretists*. The term *Eclecticism* is sometimes applied with great latitude so as to include even such comparatively harmonious systems as *Neoplatonism* but is more usually restricted to the less systematic and more loose-jointed philosophies. In 146 BC Greece became a Roman province and Rome developed philosophic ambitions without ever succeeding in constructing an independent philosophic system. It was probably in keeping with the essentially practical mentality of the Romans to refrain from speculation beyond a certain point and to trust their common sense instead of following theoretical adventure whithersoever it may lead. The most famous *eclectics* of antiquity were *Cicero* and *Seneca* (AD 5-65). Both showed marked leanings towards the *epistemology* of the *Skeptics* of the *New Academy* and the *ethics* of the

*Stoics*. *Cicero* also turned somewhat toward *Stoic pantheism* and *Seneca* has more than many people as remarkably Christian or *pagan*. Of course, the *Eclectics* of *de Rome*. Perhaps the best known of them was the Greek *Plutarch* (AD 50-120) (See *CR* *de Rome* *PLUTARCH*).

**The End of Ancient Philosophy**—In AD 59 the Emperor *Justinian* closed the school of philosophy and so brought to an end the *ancient* period in the history of philosophy. During the *middle ages* which followed the writings of the *eclectics* and especially those of *Cicero* did much to keep alive a knowledge of ancient philosophy and to interest in philosophical problems.

#### MÆDIAEVAL PHILOSOPHY

Greek philosophy had stirred a national reaction against the mythologies of popular religion and in Athens at least three Greek philosophers (*Anaxagoras*, *Socrates* and *Aristotle*) suffered for execution one of them even death on account of their alleged hostility to popular religion. In the middle ages the tables are turned. Popular religion has the upper hand and philosophy becomes the handmaid of theology. There is no independent *mediaeval* philosophy. It is not original but borrowed from the past and it is not free but subordinate to authority—the authority of books or of an organized Church. This is true more or less not only of Christianity which played the leading role in the middle ages but also of Judaism and of Islam. When philosophy was not simply denounced and ignored it was exploited in the interests of the Christian, Jewish or Mohammedan epic not to say mythology. Some would go so far as to refuse the name philosophy to thought so restricted. But it is impracticable to draw a hard and fast line. On the one hand even Greek philosophy was perhaps never entirely purged of elements of mythology. On the other hand even *mediaeval* thinkers by a subtle use of allegorical interpretation managed to fit Scripture to their philosophy instead of modifying their philosophy to fit Scripture and so gained a measure of freedom of thought.

#### PATRISTIC PHILOSOPHY

*Mediaeval* philosophers were for the most part Christian theologians and a detailed history of their views belongs to the history of Christian dogma rather than to the history of philosophy. Here our business is only with the limited philosophical aspect of that complex and interesting story. Christianity did not set out to be a philosophy but a moral and religious stimulus. Its interest was in the lowly rather than in the high brow. It was suspicious of philosophy and uttered a warning against it.

Take heed lest there shall be any one that maketh spoil of you through his philosophy (Col 2:8). And at least one Apostolic Father (*Tertullian*) not only did not mind it if his faith was unphilosophical but was almost proud of it—*credo quia absurdum*. In course of time however it was found necessary to make use of philosophy partly in order to repel the attacks of hostile philosophers partly in order to spread the gospel among philosophically minded heathens and partly in order to satisfy the needs or tastes of Christians with a turn for philosophy. Early in the 2nd century already Alexandrian Christians like Alexandrian Jews resorted to allegorical *Neoplatonist* interpretations as is clear from the *Logos* doctrine in the so-called *Gospel of St John*. Some of the *Gnostics* even tried to combine loyalty to Jesus with loyalty to *Pythagoras*, *Plato* and *Aristotle*. For some time however the chief use made of philosophy was for purposes of defence (*apologetics*). This was the case with the Church Fathers notably *Justin Martyr* (d 167), *Tertullian* (150-220), *Clement of Alexandria* (d 215), *Origen* (185-254) and above all *Augustine* (354-430).

The *Patristic* period as it is called is characterized by its *Platonic* or *Neoplatonist* tendency for which the influence of *Augustine* secured a certain predominance in Christian thought for a long time afterwards. *Augustine* had been a sceptic among other things before he became a saint so he felt it necessary to refute scepticism before attempting a constructive philosophy. His method was that adopted later by *Descartes*. There are many things he said that are dubious. But there is one thing that is indubitable even in the state of doubt, namely the actual

The chief aim of the scholastic was to reconcile Christian theology with philosophy. The first prominent Scholastic was John Scotus Eriugena (1058), He insisted on the harmony of Christianity and philosophy as God is the author of both. Under the influence of a kind of Neo-Platonic mysticism he held the doctrine that things only exist in so far as they are known. He unveiled ideas by which they are said to be known, rather than to create reality and produce the objects themselves.

This kind of view about the reality of ideas now usually called idealism was known as realism in the middle ages. (Later on realism meant and still usually means the view that material things are also real which extreme idealism denied.) In course of time the problem of the reality of universals became a burning question among the Scholastics. It was usually raised in connection with Porphyry's discussion of Aristotle's predicables but that was a matter of chance. It would probably have arisen in any case in connection with the study of the differences between Platonism and Aristotelianism. Until late in the 11th century, under the predominant influence of Platonism or Neo-Platonism, realism was the usual view. Roscelinus (1050-1111) was the first nominalist; that is to say he denied the independent reality of universals and regarded general terms as mere names. For a long period however he had no following. Anselm of Canterbury (1033-1109) was a pronounced realist. He also formulated the characteristic view of Scholasticism that faith must precede knowledge—*credo ut intelligam*.

An innovator was Abelard (1091-1142) famous for his association with Heloise. His view of universals was rather like that of Avicenna. He held that universals are embodied in the individual things. The forms or ideas however are conceived by God from all eternity. The human mind only gets to know them by abstraction from particulars. So universals exist *ante res in rebus* and *post res*. Abelard is noteworthy for his defence of doubt. He claimed a certain value for it inasmuch as doubt leads to enquiry and enquiry leads to truth. In his ethical treatise *Scito te ipsum* (Know thyself—the first separate ethical treatise in the middle ages) Abelard shows himself comparatively tolerant towards pagans, Jews and philosophers or free thinkers.

The Crusades (1097-1204) brought Christendom into contact with Eastern learning and so helped to promote a fuller knowledge of Platonism and Aristotelianism especially the latter as expounded by Arabian and Jewish philosophers. This tendency made a good beginning when in 1085 Toledo fell into the hands of the Christians who thus came into possession of numerous philosophical manuscripts. And the movement reached its climax when in the course of the 13th century Aristotelian manuscripts in the original Greek found their way gradually from Constantinople to the new centres of European learning. Aristotelianism rejected by the Church in the early part of the 13th century grew rapidly in favour especially in the Dominican order which produced the two greatest Aristotelian Scholastics namely Albertus Magnus (1193-1280) and Thomas Aquinas (1225-1274). Albertus wrote voluminous expositions of Aristotelianism with the help of Arabian and Jewish commentators especially Avicenna and Maimonides. In the realm of natural knowledge he respected the authority of Aristotle as much as he trusted Augustine in the sphere of Christian faith. In fact it was he who first distinguished sharply between *natural* and *theological* knowledge—a distinction of no little importance in the history of Scholasticism and even later.

Aristotelian Scholasticism culminated in Thomas Aquinas. He also emphasized the distinction between natural and theological knowledge between the light of reason (*lumen naturale*) and the light of revelation and even admitted in principle the autonomy of the former. In practice however he subordinated natural to theological knowledge in the sense of making the former aid to the latter. Philosophy is thus treated as the handmaid of theology and nature as the mere forerunner of grace though grace is alleged to crown nature not to reject it. The distinction though difficult or impossible to maintain turned out to be helpful inas-

much as it rendered possible a certain amount of independent thinking; the reason for this was so long as no reference was made to the contents of theological Christianity (which constituted the realia of the ecclesia). Like Aristotle Aquinas laid great stress on the distinction between matter and form though he is rather liberal in his conception of the numerous forms capable of being appropriate matter. The human soul though associated with a body is capable of separate existence. It is the lowest of the separate orders of which here is a scale ascending through the kind and degree of angels and spirits (including those which guide the stars and their courses) and culminating in the absolute form namely God. By assuming that God had conferred a measure of autonomy upon nature Aquinas further facilitated to some extent the possibility of an autonomous philosophy or science. His conception of the character of human knowledge also tended in the same direction. Instead of regarding it (as Augustine had done) as a direct divine illumination Aquinas conceived it to be produced by images which external objects deposit so to say in the soul. Empirical studies thus received some recognition. On the question of universals the view of Aquinas was that one form is embodied in all the material objects of the same class and that their matter is responsible for their particularity and multiplicity. In the case of Angels etc. that is immaterial forms there is no such multiplicity of replicas so to say—each form is unique. Our knowledge of material objects *qua* particulars comes through our senses but their form is apprehended by the intellect.

The Aristotelianism of the Dominicans was opposed by the rival Franciscan order the principal representative of which was Duns Scotus (1265-1308). He strongly opposed the intellectualism of Aquinas and repudiated the endeavour to harmonize faith with knowledge, theology with philosophy and rather emphasized their antagonism. What is true in philosophy may be quite false in theology which leaves no room for philosophical dialectics. Whereas Aquinas regarded knowledge as primary and will as dependent on knowledge Duns Scotus claims primacy for the will which he treats as the fundamental faculty of the soul. Imagination and conception are entirely subordinate to the will with which the decision always rests and which is free from all possibility of coercion. The good is above the true. And the good is good because God has declared it such (Aquinas maintained that God ordained certain things because they are good). Things are what they are because God has arbitrarily made them so. And the duty of man is to will to obey God's commands. On the question of universals Duns Scotus upheld the same kind of realism as did Anselm, Avicenna and Aquinas. The doctrine of the primacy of the will was adopted later by Descartes.

The teaching of Duns Scotus concerning the irreconcilable antagonism between philosophy and theology and concerning the arbitrary character of divine creations and decrees was carried even to greater extremes by William of Occam (d. 1347). He maintained that philosophy is utterly incapable of proving the existence of God or demonstrating His attributes. From this bankruptcy of the natural light of reason he infers the necessity of revelation. He carries his conception of the good as the arbitrary decree of God so far as to maintain that a so-called evil deed is not evil if it is done in the service of God. In opposition to the moderate realism of the Dominicans Occam revived the nominalism of Roscelinus and maintained that universals are merely subjective conceptions, all real things being individual or particular. To posit real universals in addition to the corresponding particular objects is an uncalled for duplication. It was in this connection that he formulated the familiar principle commonly known as Occam's Razor: *entia praeter necessitatem non sunt multiplicanda*—the number of entities should not be increased unnecessarily. After Occam Scholasticism rapidly declined in influence. In one form or another it continued of course and continues to this day. It has even enjoyed various revivals. But its power was broken by the onward march of that great combination of forces called the Renaissance or Revival of Learning. (See SCHOLASTICISM, KNOWLEDGE, THEORY OF.)

Spinoza (1632-1677) marks the culmination of the various tendencies of the Renaissance. He vindicated the autonomy of reason against every kind of authority, subordinating even the Scriptures to it. Rationalism expresses itself most characteristically in the attempt to connect things in continuous series or systems of events which suffer no arbitrary incursions from outside in the form of supernatural interventions. The great achievements of that classic age of science were essentially expressions of the rationalism of the 17th century. Yet the rationalism of all the great scientists of the time was fragmentary: one-sided. It was a week-day rationalism handicapped with a Sunday irrationalism. Spinoza was the complete rationalist, the prince of rationalists. He attempted to interconnect the *whole* of reality in *one* organic cosmos which suffered no cleavage into a natural and a supernatural realm, or into a work-day and a Sabbath vista. For Spinoza the world is a real universe. It is also a real cosmos, orderly through and through, subject to no arbitrariness, not even the arbitrariness of God. The rejection of the supernatural and the arbitrary constitutes the naturalism of Spinoza. But his conception of the universe avoided sacrificing any one part of it to any other of the material to the mental or vice versa. While repudiating any reality outside the cosmos (or Nature) he was careful to include within it whatever could claim reality—not only the material and the mental, but also the divine. They all have their place in the cosmic system. In fact, God is the cosmic system. For God is conceived as the Perfect Self-existent, and that is just what the cosmos or Nature is—hence *Deus sive Natura*. The All is God, and God is All. This constitutes the pantheism of Spinoza.

The way in which Spinoza arrived at his main conceptions is rather obscured by the geometric method of exposition pursued in his *Ethics*. Briefly it was this. To understand any finite object or event it is necessary to follow up innumerable conditions on which it depends. These ramify in all directions yet we can never halt for the conditions invoked are themselves dependent on innumerable others. But a world consisting *entirely* of dependent objects and events would be unintelligible inconceivable. There must be some unconditioned, self dependent absolute reality, or Substance, to account for the reality of all that is conditioned and dependent. This is usually admitted. But the traditional solution accepted by Descartes and the greatest scientists

A. I say a that God a supernatural omnipotent  
 being or Substance who has  
 But the idea of an external  
 H. Idealism revolted against  
 a notion having taken place at one  
 could find in the notion of  
 more irrefragable than the proof  
 I t's necessary to posit an  
 or accept the system of reality

the view of the multiplication of entities  
of the derivation of nothing. It was also more  
suitable to the mind of Spinoza's character for it  
brought it into relation with God. Such a view  
was of course only possible in consequence of the friendlier  
attitude toward Nature which the Renaissance cultivated as  
against the hostile association of the world, the flesh and the  
devil characteristic of medieval Christianity. With regard to  
the structure of the system, the leading ideas of Spinoza  
may be summarized as follows: God (or Nature or Substance) is  
not static but dynamic and exercises all the kinds of energy that  
there are. It alone is absolutely infinite or absolutely perfect.  
Each kind of energy that is ultimate that is irreducible to any  
other kind Spinoza calls an attribute of substance. Spinoza refers  
to an infinity of such attributes. But by infinite he means  
complete (not innumerable) and by finite incomplete or  
fragmentary. Man only knows two such attributes namely ex-  
tension and thought that is physical energy and mind energy.  
There may be others there probably are. Moreover each attri-  
bute is *infinite of its kind* that is exhausts everything of its own  
kind so that there is no physical energy outside extension nor  
mind energy outside thought.

All finite bodies and physical events are modes that is modifications or states of extension and all minds and mental experiences are modes of thought. Similarly with the other attribute if any all cosmic activities or processes are immanent not transcendent. And all apparent interactions between the modes of different attributes say that between the body and soul of man result from the fact that they are concomitant expressions of the attributes of the one substance. The order and connection of thoughts is the same as the order and connection of things. Physical effects should be traced to physical causes and mental experiences to mental causes. The various finite modes come into being and pass away but not into nothingness—for the One remains in which the many change. God as conceived by Spinoza is not a personal God not however because He is less but because He is infinitely more than any personality known to man. (See SPINOZA PANTHEISM ETHICS HISTORY OF KNOWLEDGE THEORY OF)

**Leibniz** (1646-1, 16) was influenced mainly by his faith in the permanent reality of individual souls. His philosophy accordingly is so constructed as to secure the ultimate reality of individuals and to assure their permanence. To this end two things were felt to be necessary. He had to dissociate souls from physical atoms and to treat each individual soul as a kind of substance or self contained thing. The Cartesian identification of matter with extension (which was widely accepted then) prompted Leibniz to deny the reality of matter altogether. For matter is then infinitely divisible and no real atom, nothing ultimate and really indivisible can be conceived for the construction of the composite bodies of ordinary observation. From this he concluded that all space or all material bodies are mere subjective appearances not objective realities. Reality according to Leibniz consists entirely of souls or spirits of all degrees of development. These are the real 'atoms' or individuals, real unities not made up of parts. Some of them have only a very low degree of consciousness or sub consciousness, they are in a state of chronic somnolence so to say, some are in something like a dream state, others are more awake, have clear thoughts, or are even self conscious and God, the monad of monads, is supremely conscious and active. There is an infinity of monads, their gradation is continuous without a break and no two are

[illegible]

Like Descartes Leibniz follows strictly mechanical methods in dealing with physical problems but he conceives mechanism to be in the service of teleology and his general outlook of course was essentially teleological. His conception of the relation between the supreme monad and the other monads is obviously supernatural. In his philosophy as in his public activities Leibniz tried to bring together too many different elements to succeed in uniting them in one system. Leibniz is also famous for his optimism that is for holding the view that the actual world is the best of all possible worlds. What he meant was that the pre-established harmony actually established by God was chosen by Him as the best possible out of an endless variety of possibilities in view of the purpose which He had in view. This does not imply that each thing regarded by itself is the best of its kind or even good. It means only that in order to make any one thing better the entire scheme of things would have to be different and as a whole rather worse. (See LEIBNIZ IDEALISM KNOWLEDGE THEORY OF OPTIMISM)

## FROM LOCKE TO HUME

**Locke** (1632-1704) has the distinction of having given a decidedly epistemological turn to modern philosophy. He relates that five or six friends used to discuss philosophical or theological problems with him but fruitlessly. So it occurred to him that before we set ourselves upon inquiries of that nature it was necessary to examine our own abilities and see what objects our understandings were or were not fitted to deal with. By extending their inquiries beyond their capacities people only raise questions and multiply disputes which never coming to any clear resolution are proper only to continue and increase their doubts and confirm them at last in perfect scepticism. Locke attempted to carry out the task which he set himself by means of a descriptive account of human ideas or experiences of which he drew up a detailed inventory in his *Essay concerning Human Understanding* (1690). Locke uses the term *idea* for any object of the understanding: any object as experienced and directly or indirectly he traces all ideas to experience. This constitutes his empiricism. He rejects innate ideas maintaining that prior to experience the mind is like a blank paper but he credits the mind with certain powers. Ideas are of two kinds in respect of their origin. Some are induced by sensible objects—they are 'ideas of sensation'. Others result from reflection upon such ideas of sensation—they are ideas of reflection. And the mind not only reflects but also combines the given simple ideas into complex ones.

Locke believes that there are external things. But the mind does not apprehend them directly. Ideas of sensation are at best only "appearances of things, only copies of them mediating between them and the apprehending mind. And this is true only of ideas relating to primary qualities (extension, figure, number,

more over the idea of creation relating to secondary  
and tertiary ideas are simply secondary or subjective  
and therefore the primary quality and are not  
created by the mind. It confirms the simple ideas of  
order and relation to be created at all times  
and the ideas of space and time. The idea of a  
necessary correspondence between the  
secondary and tertiary ideas is given on—ie cannot  
be created by experience and he admits that it  
is a necessary condition of both physical  
and mental in

On the other hand, each man is doubly sure by intuition  
 re... by intuition presupposing it. Of God's exist-  
 ence... demonstration to our own exist-  
 ence... explained without reference to Him as its cause. But  
 little same the real essence of which is unknowable and  
 Logic is apt to doubt science or physical to be out of our  
 reach beyond merely empirical limit. (See LOGIC, EMPIRICISM  
 KNOWLEDGE THEORY OF PSYCHOLOGY HISTOR OF)

**Berkeley** ( 6 - 1751 ) set himself the task of opposing the mechanistic methods of explanation generally accepted in his time in consequence of the tradition set by the great pioneers of modern science. He feared that that way lay materialism and atheism. But it was Locke's Essay that served him chiefly as the text of his criticism especially in his *Principles of Human Knowledge* ( 1710 ) and the *Three Dialogues* ( 1713 ). Locke had maintained that our idea of primary qualities resemble their external objects whereas those of secondary qualities have no corresponding object. Berkeley objected that both kinds of ideas are equally dependent on the mind and there is no more need or justification to assume the objective existence of primary than of secondary qualities. Moreover it is absurd to suppose that an idea can resemble anything that is not an idea. And if it is superfluous to assume the objective existence of primary qualities corresponding to certain ideas of sensation it is even more unnecessary to assume with Locke the independent existence of material substance of which strictly speaking we have no idea at all.

Locke had treated ideas of sensation as things which mediate between the knowing mind and corresponding material objects which they resemble where there is real knowledge but Berkeley denounces this distinction between ideas and external objects as the very root of scepticism — for how can it be known that the things which are perceived are conformable to those which are not perceived (*Principles* 86). For Berkeley the ideas are the objects of knowledge and there is nothing beyond them. All the choir of heaven and furniture of earth in a word all those bodies which compose the mighty frame of the world have not any substance without the mind their *being* is to be perceived or known consequently so long as they are not actually perceived by me or do not exist in my mind or that of any other created spirit they must either have no existence at all or else subsist in the mind of some Eternal Spirit (*Ibid* § 6). With the substantiality of matter its causality is also rejected. One idea of sensation cannot *cause* another it can only *suggest* it.

The fire which I see is not the cause of the pain I suffer upon my approaching it but the mark that forewarns me of it (*Ibid* § 65) And if one asks how it comes about that there appear to be such regular connections between divers ideas the answer is that this is done in virtue of an arbitrary connection instituted by the Author of Nature (*Theory of Visual Language* § 43) For spirits or minds are active agents in fact the only ones

Mechanistic explanations are therefore illusory. And if one objects (as Hume did soon afterwards) that there seems to be no more reason for assuming a mental substance than a material substance ideas being the only things known then Berkeley's reply is as follows 'I *myself* am not ideas but a thinking active principle that operates about ideas. I know that I perceive both colours and sounds that a colour cannot perceive a sound nor a sound a colour that I am therefore one individual principle distinct from colour and sound and all other sensible things or inert ideas' (*Third Dialogue*). He admits however that he has no 'idea' of minds or spirits only a

no ion. Anyw the net res l of Berkeley's reduction is ideal philosophy according to which reality rests in God, other spirits or things which He has created and which produce ideas which He has produced and which are apprehended in certain sequences of ideas as decreed by Him. (S. BERKELEY IDEALISM KNOWLEDGE THEORY)

Hume (1711-1766) pursued the problem and method of Locke to their extreme conclusion in the sense that he showed that the kind of empiricism which Locke had advocated leads to positivism in science and scepticism in philosophy. It is one of the ironies of history that the book which Berkeley wrote in order to prevent or to cure scepticism actually infected Hume with it.

He professes [so writes Hume of Berkeley] in his title page to have composed his book against the scepticism as well as the atheists and freethinkers. But though all his arguments tho otherwise intended are in reality merely sceptical appears from this that they admit of no answer and produce no conviction. Their only effect is to cause that momentary amazement and irresolution and confusion which is the result of scepticism. (*Enquiry Concerning Human Understanding*, section 1, part 11.) Berkeley had contended that there is not sufficient evidence for assuming material substances or material causality as we have no ideas of either but he defended both the substantial nature and causal power of minds or spirits. Hume argued that the same reason which led Berkeley to reject material substances and material causes are also valid against the assumption of mental substances and mental causes.

Berkeley had tried to save mental substances and mental agency by pleading that we have notions of them apprehended by reason though not ideas of experience. But Hume rejected this view of a radical distinction between reason and experience and submitted everything even rational judgments to the test of experience and insisted on accounting for everything in terms of experience. He accordingly denied the certainty even of so called mathematical knowledge and reduced all alleged knowledge or certainty to mere probability. Causality itself he explained away as habitual association of sequent impressions or ideas and substances as due to the mistaking of similar recurring impressions for continuous impressions of the same thing. (See HUME KNOWLEDGE THEORY OF SCEPTICISM)

#### FROM KANT TO HEGEL

Kant (1724-1804) is the founder of the critical philosophy or of transcendentalism. The stress which Descartes had laid on thought or subjective experience in basing his whole system on the *cogito ergo sum* quite naturally resulted in a divorce between ideas on the one hand and the external world on the other. This is clear alike in the idealism of Leibniz and Berkeley in the empiricism of Locke and in the scepticism of Hume. The only philosophers of importance who avoided this predicament were Spinoza on the one hand and Thomas Reid (1710-96) and the Scottish school on the other. But the alleged atheism of Spinoza robbed him of real influence and the common sense philosophy of the Scottish school was not sufficiently subtle to impress speculative minds. Kant attempted a new way of bringing thought and reality into touch once more. Kant himself liked to stress the critical character of his philosophy as the new element which he contributed and consequently called his three great works *critiques*. He described all his predecessors as dogmatic philosophers because they did not begin their philosophy with a critical examination of human capacity for knowledge.

The way in which Kant attempted to reunite knowledge with reality was brief as follows. Known objects according to Kant are a multiplicity of sense materials supplied to the apprehending mind which synthesizes them in accordance with certain forms of intuition (space and time) and certain categories of thought (substance and attribute cause and effect etc.) What the multiplicity of sense materials may be before the mind has synthesized them, we do not and cannot know. But they are not produced by the mind they are only apprehended and moulded by it—they are or pertain to 'things in themselves'. On the other hand, the

form of intuition and the categories of thought are ways in which the individual or our nature moulds or systematizes the raw material of sense materials so as to adapt them to our own unity. The forms are *a priori* or transcendental in the sense that they are not derived from experience and without them it would be impossible without them. On the other hand the multiplicity of sense material is *a posteriori* or only known in experience and known through it (though not known in itself).

The various *a priori* forms of apprehension are not peculiar to the unity of individual minds as such but rather express the unity of our conditions in general in which individual mind participates but which is super-individual. That is how it comes about that there is universal agreement in the use of the *a priori* form and categories instead of individual variations. Any human knowledge does not extend to the intrinsic nature of ultimate reality or things in themselves but only to their appearances as moulded by the forms of intuition and categories of thought. In Kant's language human knowledge is of phenomena not of noumena or things in themselves. And any attempt to apply the *a priori* or transcendental forms to what does not fall within the realm of possible human experience Kant condemned as transcendent. The existence of God and the immortality of the soul *e.g.* are beyond the realm of possible human experience and therefore of knowledge though what cannot be *known* may yet be *believed* as a matter of *faith*.

And it is on such practical reasons that Kant based the beliefs in the existence of God in the freedom of the will and in the immortality of the soul. These things according to Kant are postulates of morality. The categorical imperative the unconditional character of the sense of duty can only be understood and justified on the assumption or faith that we are free to do or can do what we ought to do that there is a God who can duly correlate virtue with happiness and that there is a hereafter in which the injustices of the present life may be adjusted. Kant's moral philosophy brings out with special clearness a striking feature of his whole method of philosophizing. He does not doubt the validity of the sense of duty or the categorical imperative he acknowledged it and only draws out its implications or conditions. Similarly Kant did not question the reality of the external world as conceived by contemporary (Newtonian) science he accepted it (as Hume the sceptic would not) and tried to elicit the conditions of the validity of that science. (See KANT ETHICS HISTORY OF KNOWLEDGE THEORY OF TRANSCENDENTALISM RATIONALISM)

Fichte (1762-1814) agreed with Kant in ascribing to mind or consciousness in general (or absolute self as he preferred to call it) the forms of intuition and categories of thought which characterize objects of knowledge. But he held that Kant had not gone far enough. Kant had recognized things in themselves or noumena independent of consciousness and furnishing the sense materials for experience. These noumena could only be vaguely thought about not perceived except as moulded in the forms of knowledge supplied by consciousness. Fichte however held that even the thing in itself is also the product of consciousness. The absolute self (in which individual minds participate) is the source of the whole of experience not of its forms only. It divides itself in experience into a knowing self and a known object because the development of the moral life needs objects as obstacles to be overcome by moral effort prompted by a sense of duty. Moreover there must be many minds or selves if there are to be mutual duties. But they are all the expressions of one moral order which is the absolute self or God. (See FICHTE IDEALISM) A philosophy essentially like that of Fichte was taught subsequently by R. Eucken (1846-1926).

Schelling (1775-1854) reverted more or less to the fundamental conception of Spinoza and tried to vindicate the reality of the material against the efforts of so many modern philosophers to reduce it to mere appearances or ideas. He contended that the beauty of the material world (or Nature in the narrower sense of the term) gave it a sufficient claim to have a reality of its

own so he conceived of Nature as expression or manifestation of the Absolute in the same way as consciousness or mind. But regard mind as this or that depends on the Absolute in the same kind of way as the two spheres of matter and thought were conceived by Spinoza to be related to substance. The Absolute however cannot be conceived as a thing in itself, neither as a mere principle, but some are common to both and identical in both. Hence the name idealism proper to which Schelling was commonly known (See HEGEL IN IDEALISM).

**Hegel** (1770-1831) is the founder of logical Idealism or Pantheism. He rejected the unknown thing in itself of Kant and he equated unknown identity or Absolute which according to Schelling manifests itself in Nature and mind. He denied the oppositions of ultimate reality and insisted that the entire universe can be perceived by thought. Mind and Nature are no merely manifestations or expression of an otherwise unknown Absolute, they are the Absolute itself. Moreover mind and Nature according to Hegel are not two distinct or parallel realities but integral components of one process of self-revelation. Mind need for its own development an objective world or Nature on which to exercise itself, but this objective world is itself mental, something that is at once appearance and reality—the real is rational and the rational is real. The development of this rational reality is a kind of dialectic proceeding by the method of the *thesis*, *antithesis* and *synthesis* or *position*, *negation* and *reconciliation*. Some thought occurs, it is opposed by another thought which also turns out to be inadequate, but what is true in each, the *thesis* and the *antithesis*, is harmonized and made mutually supplementary in another thought which synthesizes them, e.g. becoming is such a synthesis of being and not being.

The whole world according to Hegel is made up of such opposites which are reconciled. The general scheme of the cosmic dialectic is this: First comes mind in itself, or the system of categories which are conceived by Hegel not as mere forms of thought by which unknown things in themselves are apprehended but as ultimate realities; next comes mind for itself, that is Nature as the self-externalization of mind in itself; lastly comes mind in and for itself, that is mind or consciousness coming or returning to itself. This last phase the mind's coming to itself has a number of grades or stages. These are individual mind or subjective consciousness, objective mind or social consciousness as expressed in law, morality, the State, and absolute mind or consciousness active intuitively in art, imaginatively in religion and intellectually in philosophy. Hegel's conception of the cosmic process as a rational dialectic stimulated new views of history and consequently a new interest in it. (See HEGEL KNOWLEDGE THEORY OF IDEALISM)

#### GERMAN PHILOSOPHY SINCE HEGEL

**Materialism**—Various influences combined to occasion a tendency towards materialism about the middle of the 19th century. Idealism had on the whole sided definitely with conservatism in religion and politics. Hegel's dictum, the real is rational, was readily exploited in a reactionary sense beyond anything that Hegel intended, conservative as he himself had been. The generation inspired by the revolutionary tendencies of 1848 resented this kind of idealism. Stimulated by the microscopic biology of Schwann (who showed the cell to be the unit of plant and animal organisms) by the chemical researches of Liebig by Schleiden's rejection of vitalism and by the physical experiments of Mayer, Joule, Colding and Helmholtz which resulted in the discovery of the principle of conservation of energy, the scientific spirit of the age revolted against the idealists' indulgence in romantic speculation. Industrial progress, advance in the technical arts and the consequent improvement in economic and material conditions also helped to stimulate special interest in things material. And the doctrines of the French materialists of the 18th century, La Mettrie (1709-51), Holbach (1723-89) and Cabanis (1757-1808) were ready at hand to be taken up and developed. J. Moleschott (1822-93) described the whole cycle of life in

terms of matter and energy. Matter conditions life, life conditions thought, and though conditions the will to improve life. This is a condition as the remainder of human destiny.

K. Vogt (1804-91) supplemented Moleschott's dictum, no life without matter, with the statement that thought is related to the brain in the same way as life to the liver. The same thing has been said recently by C. F. Vogt and did not pretend to know exactly the same aim, the production of thought. L. Buchner (1804-93) was the most important of this group and his *Force and Matter* (1855) was considered for a considerable time as the source book of materialism. He identified force of every kind with love and regarded everything as the product of matter and motion which are designative but not separable. He rejected the idea held that life is spontaneously generated out of matter under certain conditions and that mental process is only a radiation through the cell of the grey substance of the brain of a motion set up by external stimuli. H. Crolbe (1819-33) rejected everything supernatural and all transcendental notions. But he maintained that the world cannot be derived from any one principle such as Buchner's force and matter, but only from a plurality of irreducible principles including material atoms, organic forces, mental elements, etc. which between them constitute a harmonious and purposive natural system. Like the other materialists in this group he was inspired by an enthusiasm for humanity and the amelioration of human conditions. (See MATERIALISM)

**Schopenhauer** (1788-1860) is the philosopher of voluntarism and pessimism. Just as Hegel his senior contemporary had identified ultimate reality with reason, so Schopenhauer on the contrary identified it with will and irrational will to boot. He too claimed to be developing the philosophy of Kant. For Kant like Descartes and others before him had maintained the primacy of the will on which the whole moral philosophy (including the moral postulates) was based. Will then according to Schopenhauer is the sole reality. Moreover it is universal or will in general (analogous to the consciousness in general of Kant and the German Idealists). There are really no individual things or wills. For individuality is bound up with differences of time and place which had been shown by Kant to be not real constituents of things in themselves but merely forms of their appearance. Individuality is thus mere illusion. Again Schopenhauer like Kant agreed with the Christian view that the will is essentially evil. It is a will to live at any cost and knowledge or reason is merely an instrument which it has invented to serve its own evil ends. But there is no satisfying the will to live. All the pains taken to satisfy any desire do not really avail. For the satisfaction of any one desire is only the beginning of another and the quest is infinite. So life is a welter of painful strivings and unsatisfied cravings which vastly exceed its moments of satisfaction or happiness. The remedy is a kind of Buddhist self-renunciation. By realizing the illusoriness of the individual self and the vanity of its quest for self-satisfaction man may see through the vanity of life with all its values and pursuits. (See SCHOPENHAUER PESSIMISM)

**Fechner** (1801-87) developed the philosophy known as Panpsychism, that is the view that the universe is a system or society of souls of which God is the highest and all comprehensive soul. According to Fechner material bodies are souls as they appear to other souls, whereas each soul as experienced from within is psychical. In this way he tried to save the reality of matter as well as of mind in psychophysical entities of which they are the outer and the inner side respectively. But he regarded the two sides as parallel without any interaction, and it was largely due to his influence that many psychologists adopted psychophysical parallelism as the working hypothesis in psychology. Fechner tried to combine pantheism with something sufficiently like the monadology of Leibniz to safeguard the interests of finite souls. He identified God with the soul of the universe and regarded it as embracing all other souls just as larger bodies contain smaller bodies and nature contains them all. (See FECHNER PSYCHOLOGY HISTORY OF)

**Lotze** (1817-81) elaborated a philosophy which may be

In his work on the philosophy of religion, Lotze agreed with Kant's view that the world is not a mere collection of objects but a system of ideas. He held that the world is a system of ideas, and that the objects of the world are ideas. Lotze's philosophy is a form of idealism, and he is often regarded as a precursor of the phenomenological movement. Lotze's philosophy is a form of idealism, and he is often regarded as a precursor of the phenomenological movement. Lotze's philosophy is a form of idealism, and he is often regarded as a precursor of the phenomenological movement.

**Hartmann** (1842-1906) adopted and developed Schopenhauer's voluntarism and pessimism. For Schopenhauer reality is essentially will which produces knowledge or representation as an instrument for its satisfaction. For Hartmann however representation is on a level with not subordinate to will. To either they constitute the unconscious which is the absolute in his system. With the development of the unconscious is two components differentiate gradually and the unconscious becomes conscious, self-conscious and realize the tragedy of the will to live. The remedy is so to set the two components of the unconscious will and representation into mutual antagonism as to secure eventually their mutual annihilation and eternal peace from the restless and unsatisfying pursuits of life. (See HARTMANN)

**Nietzsche** (1844-1900) was influenced chiefly by Kant, Schopenhauer and Darwin. He agreed with Schopenhauer's main theses but drew a different moral from them. Nietzsche even more than Schopenhauer so interpreted Kant's theory of knowledge as to deny the very possibility of knowledge and to reduce all so-called knowledge to mere fiction or artistry. The human mind in the very act of apprehending reality transforms it.

Truth (says Nietzsche) is not something which is already there to be found or discovered; it is something which has to be created—it is man-made as the Pragmatists said after him. This does not mean that he lumps all human beliefs together indiscriminately. Only in place of the usual distinction between true beliefs and false ones Nietzsche would substitute the distinction between those which are useful and those which are not but without in any way holding that the useful is true even as a matter of probability.

The epistemological side of Nietzsche's philosophy was developed in the fictionism of Vaihinger's *Philosophy of As If* (1911 Eng. trans. 1926). Ontologically Nietzsche agrees with Schopenhauer in identifying all reality with will. It is will that struggles for existence in animate and inanimate nature. For Nietzsche however this will is not merely a will to live but a will to power. This universe is a monster of energy without beginning or end. Nietzsche accepted will to power as ultimate reality because his experience convinced him of the reality of desires and impulses as of nothing else and he considered these a sufficient guide to philosophical construction. Like Schopenhauer he frequently paints the world in sombre colours. But the shortcomings of the world stimulate him instead of depressing him. And far from accepting Schopenhauer's ideal of a Buddhist saint, he regarded the world as a kind of Greek tragedy affording ample opportunity for heroes to show their mettle. Hence his gospel of energetic life and his ideal of a 'superman' who shall surpass the present type of man as much as man surpasses the ape. (See NIETZSCHE)

**Wundt** (1832-1921) began by insisting that human experience

is a combination of subjective and objective factors are essential to the combination. The factor may be distinguished by abstraction and in philosophy the objective factors or objects are not actually abstracted but they come to be regarded as independent things. But this is an error for the whole of our experience is in our ideas and all that reason posits behind or beyond phenomena must be regarded as transcendent. In the basic reality in experience the most proper being of the individual subject is will though it is never entirely divorced from feeling and idea. There are two grades of will namely impulsive will and voluntary will. Even impulsive will need training, care or to be ended and therefore an idea but no conscious adoption of a motive which pertains to voluntary will. He attributes impulsive will to all organisms and consequently insists that in organic evolution teleology precedes mechanical final causes precede and originate mechanical or efficient cause. Wundt describes not only attention but also thinking as will. For it is activity and all activity is will. (The conception of his will to believe was elaborated by William James.) Wundt in fact regards the soul as activity not substance—it is the entire mental activity associated with a system of bodily activities. The body itself is only an object distinguished by abstraction from the complete experience of which soul is the subjective factor. There is consequently no psychophysical opposition or interaction only a psychophysical parallelism. Human knowledge is limited to experience or phenomena or ideas. Reason does indeed transcend experience. But it can only posit ideals which are matters not of knowledge but at most matters of faith. One such ideal is God conceived as the world will. (See WUNDT PSYCHOLOGY HISTORY OF)

**Neo Kantianism**—The attempt to correct at once the materialism of the time and the absolute idealism which had partly provoked it led to a revival of interest in the philosophy of Kant and a concentration on the problems of knowledge. The movement was initiated by O. Liebmann (1840-1911). In his book *Kant und die Epigonen* (1865) every chapter ends with the refrain we must therefore return to Kant. F. A. Lange (1828-1905) advanced the movement by means of his *History of Materialism* (1866) in which he attempted to refute materialism by means of arguments based on Kant's theory of knowledge and its repudiation of all knowledge of the ultimate nature of reality or things as they are in themselves. He insisted that the matter atoms forces etc. by means of which materialists try to account for all things are not ultimate realities but only auxiliary conceptions of science. In 1871 H. Cohen (1842-1918) published his book on *Kant's Theory of Experience* and soon became the leader of the whole movement. He was joined by P. Natorp (1854-1924) his colleague in the University of Marburg where Lange too had been professor and the movement consequently came to be known as the Marburg School of philosophy. The chief representative of Neo Kantianism at present is E. Cassirer (1874- ) It cannot be said that the Neo Kantians are agreed on all points. Far from it. What is common to them is the recognition of the importance of understanding Kant and developing his transcendental method. Cohen in particular attempted to do without Kant's aesthetic to dispense with the assumption of a given sense material and to begin at once with the transcendental logic. There is no object then to be known what becomes known only becomes an object in becoming known. Nothing is independent of thought. For thought and being are identical and the judgment is the unit of both. (See NEO KANTIANISM)

#### POSITIVISM AND EVOLUTIONISM

**Comte** (1798-1857) was the founder of 'Positivism' that is the view that knowledge is limited to the objects of direct observation or experience. This view is very like the empiricism of Locke and his successors. Comte's positivism however was the outcome rather of the influence of Kant's philosophy according to which human knowledge (as distinguished from faith) is limited to phenomena and cannot penetrate to noumena or things in themselves. What is beyond experience Comte insisted is unknowable. It is consequently best to concentrate on tasks

RECENT AND CONTEMPORARY PHILOSOPHY

**The New Realism**—In Germany it was idealism that provoked materialism and materialism occasioned that revival of epistemological interest which produced Neo Kantianism. With British and American philosophy the case is rather different. It was the materialistic tendencies of empiricism agnosticism and evolutionism that provoked the idealism of the Neo Hegelians and the new realistic tendencies in epistemology have come as a revolt against idealism generally and subjective idealism more particularly. The present movement was started mainly by G. E. Moore and B. Russell and has been taken up eagerly by many others in Britain and in America. These thinkers differ in their views in some respects but they agree in their endeavour to vindicate the independent reality of the objects of human knowledge, and especially of the objects apprehended in perception. (See KNOWLEDGE THEORY OF.)

**Bergson** (1859- ) is the founder of what is variously known as the philosophy of change or creative evolution or of duration. Like the naive realist philosophers his main aim is to vindicate the prima principle of our mind and freedom in human nature against the mechanistic tendencies of modern science. Somewhat like Fichte he conceives of ultimate reality as something which is determinate though conscious or matter but from which both consciousness and matter are derived. This ultimate reality is a process, a flux, a creative evolution or real duration. It is not an inaccessible absolute which can be apprehended by man. In the absolute we live and move and have our being. The knowledge we possess of it is incomplete no doubt but not erroneous or relative. It is reality itself in the profoundest meaning of the word that we reach by the combined and progressive development of science and philosophy. Materiality and spirituality are resultants of processes in opposite directions. Spirituality is the process of concentrated activity in which the past interpenetrates the present; materiality corresponds to a relaxation of this activity.

The evolution of life has taken three divergent directions: the vegetative, the intuitive and the intelligent or rational. These are not successive stages but divergent lines of evolution. Instinct is a faculty of using organic instruments; intelligence is a faculty of making and using inorganic tools. Instinct is a kind of unconscious practical knowledge of things; intelligence is conscious thought about relations. Owing to its original function of making tools out of inert matter intelligence when it develops its theoretical side tends to regard the whole of reality as though it were a dead mechanism. This can be corrected by means of intuition which is instinct become self-conscious and capable of reflecting upon its objects. It is the function of philosophy to seize, expand and unite such fleeting intuitions which reveal the spiritual life. But intuition must not be divorced from intuition nor science from philosophy. They must be brought into close relationship if we are to avoid cold mechanism on the one hand and illusory mysticism on the other. For Bergson not perception but memory is typical of the spiritual or conscious. Perception is simply incipient or nascent action, not consciousness. Memory is real duration in which the past gnaws into the future. (See BERGSON)

**B. Croce** (1866- ) sets out from the Cartesian or rather Augustinian contention that thought is what we are most sure of and then proceeds like the German idealists to maintain that it is the only reality that need be assumed. By thought however he does not mean merely the thought of finite individuals. Like most idealists he posits a universal mind which is more than any finite individual thoughts can be but which is immanent in them. And whereas Hegel conceived of the dialectic of universal thought as essentially logical in character though he could not avoid conveying the impression that he also regarded it as a process in time, Croce definitely conceives the cosmic thought process as a process in time and identifies reality or philosophy (for the two are essentially the same in such an idealistic scheme) with history. Like Bergson and James Croce rejects the conception of a static unchanging Absolute, a block universe complete once for all. Ultimate reality as he conceives it is incessantly changing ever active always creative. This cosmic activity has no beginning and no end but proceeds in cycles. The objects to which thought is always directed are themselves the creations of thought. In fact the process of thinking the object of thought and the distinction between the act and the object of thought are all of them parts of the same total experience and it is only by a kind of abstraction that a world of objects is set up as an independent world over and against the world of thought.

In reality the whole universe is just Mind or Spirit and all differences and distinctions are within it. Of the activities of mind there are two main types namely theoretical and practical activities. Theoretical activity is of two principal varieties namely intuition and conception. Intuition is the act of creating the materials of thought and is exemplified most clearly in the creative imagination of the artist. There is no sense material

supplied to the mind from outside according to Croce the mind just has in it notions which constitute the material on which conceptual thought operates. Conception or conceptual thinking is the activity which creates and traces relations between intuitions. But the two intuition and conception are only distinguishable not separable. Intuition without conception would be blind; conception without intuition would be empty. The practical activities are all of them volitional processes or functions for there can really be no physical activities in a purely spiritual universe. And like the theoretical functions they also have two aspects or components namely a particular or individual aspect and a universal aspect which are distinguishable but not separable. (See CROCE IDEALISM NEO-HEGELIANISM)

**Alexander** (189-1938) was the first British philosopher to attempt a system of philosophy and that after the prophets had confidently asserted that there would be no more system building in philosophy. His *Space Time and Deity* (2nd ed. 1928) develops a philosophy which incorporates the new conceptions of space time and of emergent evolution and leads up to a kind of pantheism not altogether unlike that of Spinoza. Ultimate reality is Space Time of which space alone and time alone are mere abstractions. Space Time is a kind of ocean whose whirlpools constitute particular objects. Things in other words are differentiated complexes of motion within the one comprehensive system of motion. Space Time has certain pervasive or categorical properties (existence universality relation order substance quantity number motion etc.) which characterize everything. Besides these there are various empirical qualities which distinguish different classes of objects and which emerge only under special conditions. They form a hierarchy. What happens in this Space Time spontaneously differentiates into finite collocations of point instants. The simples of these consist of motions of different velocities and extents of motion. When these objects form certain patterns there emerges the quality of materiality when certain other conditions are added there emerges colour and so on.

When certain physico-chemical complexes arise life emerges out of certain configurations of living complexes; consciousness emerges. In this hierarchy of objects those that have the higher qualities also have the lower qualities. But they experience them differently—they enjoy their highest quality immediately and inwardly but only contemplate the lower qualities more or less externally. By reasonable extrapolation we may assume that there are higher qualities than consciousness. And the highest of such conceivable qualities is deity. As consciousness is the highest quality of man so deity is the highest quality of God whose body is the whole universe. God is the whole universe as evolving the quality deity. As time is never complete higher qualities continue to emerge and so God is never complete. The world with its misus towards deity stirs in us a longing for God with Whom we are in communion. And practical religion consists in doing our duty so as to advance the progress of the world towards deity. The triumph of good over evil in human affairs is one of the conditions of the emergence of deity and deity is on the side of goodness. The right attitude towards life is that of intellectual acquiescence coupled with practical efforts towards its amelioration even though the springs of pain may never be sealed. As to the relation of the finite many to the infinite One—the One is the system of the many in which they are conserved not the vortex in which they are engulfed. (See QUALITIES Primary Secondary and Tertiary)

PHILOSOPHY AND PHILOSOPHICAL STUDIES

Philosophy is a certain term of the mind and corresponds to a certain kind of activity of the mind of certain persons in the world. It can be characterized by a universal principle which is present in itself in the history of Greek thought from the beginning of knowledge and culture in the East. The expression is based in the gradual specification of the term. The etymologies of the word (the verbs *φιλοσοφειν* or *φιλοσοφειν* Herodotus and Thucydides) imply the idea of the *pur suit* of knowledge, but the distinction between the *σοφος* or wise man and the *φιλοσοφος* or lover of wisdom appears first in the Platonic writing and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophon and is doubtless to be attributed to the historical Socrates. But the word has lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

to a higher ground or author of things. This inquiry which has been called epistemology may be said to form part of the general type of metaphysics or at all event a pendant of it. By the gradual sitting out of the physical sciences philosophy has come to be conceived as the inquiries grouped under metaphysics or philosophy. There would embrace according to the Western scheme long current in philosophical textbooks ontology proper or the science of being as such with its three branches science of (1) being, (2) psychology or metaphysics and (3) rational (or natural) theology along with the three chief forms of being—the soul, the world and God. Subsidiary to metaphysics as the central inquiry would be the sciences of logic and ethics to which may be added aesthetics constituting three normative sciences—sciences that which do not primarily describe facts but rather prescribe ends or set forth ideal.

In sum then we may say that philosophy has come to be understood at least in modern times as a general term covering the various disciplines just enumerated. We shall first of all attempt to differentiate philosophy from the special sciences and afterwards proceed to take up one by one what have been called the philosophical sciences with the view of showing how far the usual subject matter of each is really philosophical in its bearing. The order in which it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge and ontology, then logic, aesthetics and ethics. Finally the connection of the last mentioned with politics (or to speak more modernly with jurisprudence and sociology), with the philosophy of history and the philosophy of religion will call for a few words on the relation of these sciences to general philosophy.

Philosophy and Natural Science.—In distinguishing philosophy from the sciences it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject matter different from and in some obscure way transcending the subject matter of the sciences. Now that psychology or the observational and experimental study of mind may be said to have been definitively included among the positive sciences there is not even the apparent ground which once existed for such an idea. Philosophy has no other subject matter than the nature of the real world as that world lies around us in everyday life and lies open to observers on every side. But if this is so it may be asked what function can remain for philosophy when every portion of the field is already lotted out and enclosed by specialists? Philosophy claims to be the science of the whole but if we get the knowledge of the part from the different sciences what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself: it has to show that the subject matter which we are all dealing with in detail really *is* a whole consisting of articulated members. Evidently therefore the relation existing between philosophy and the sciences will be to some extent one of reciprocal influence. The sciences may be said to furnish philosophy with its matter but philosophical criticism reacts upon the matter thus furnished and transforms it. Such transformation is inevitable for the parts only exist and can only be fully *re* truly known in their relation to the whole. A pure specialist if such a being were possible would be merely an instrument whose results had to be co-ordinated and used by others. Now though a pure specialist may be an abstraction of the mind the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified and fruitfully applied in their own sphere of investigation and in proportion as this is the case it becomes necessary for their theories to be co-ordinated with the results of other inquirers and set as it were in the light of the whole. This task of co-ordination in the broadest sense is undertaken by philosophy for the philosopher is essentially what Plato in a happy moment styled him, *συνολτικος* the man who takes a synoptic or comprehensive view of the universe as a whole. The aim of philosophy (whether fully attainable or not) is to exhibit the

and ordering of the parts of the whole. The philosopher is not a collector of individual facts, but a seeker of the general principles which are involved in the facts.

For the first time, what has been said is a new way in which the world is seen. The world is not a collection of individual facts, but a system of relations. A fact is not an isolated entity, but a relation to other facts. The relations are multiplied in the progress of knowledge. The nature of the world is not a fixed fact, but an indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the facts of the world cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite without investigating in what sense the existence or the infinity of this *Udang* as Kant called it can be asserted. In the same way physics may be said to assume the notion of material atoms and forces. The same and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy as a theory of knowledge to submit such conceptions to a critical analysis with a view to discover how far they can be *thought out* or how far when this is done they refute themselves and call for a different form of statement if they are to be taken as a statement of the ultimate nature of the real. The first statement may frequently turn out to have been merely provisionally or relatively true. It is then superseded by, or rather inevitably merges itself in a less abstract account. In this the same facts appear differently because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing we have said as an individual fact, and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe or in Spinoza's phrase *sub specie aeternitatis*. In strictness there is but one *res completa* or concrete fact, and it is the business of philosophy as science of the whole to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences including as we shall see the science of psychology. The sciences one and all deal with a world of objects but the ultimate fact as we know it is the existence of an object for a subject. Subject object knowledge or more widely self consciousness with its implicates—this unity in duality is the ultimate aspect which reality presents. It has generally been considered therefore as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation or in Kantian phraseology a theory of its possibility. Any would be theory of the universe which makes its central fact impossible stands self condemned. On the other hand a sufficient analysis here may be expected to yield us a statement of the reality of thing *in its last terms* and thus to shed a light backwards upon the true nature of our subordinate conceptions.

**Psychology Epistemology and Ontology**—This leads to the consideration of the main divisions of philosophy—psychology (*qv*), epistemology (theory of knowledge) and ontology. A special relation has always existed between psychology and systematic philosophy but the closeness of the connection has been characteristic of modern and more particularly of English thought. The connection is not difficult to explain seeing that in psychology or the science of mind we study the fact of intelligence (and moral action) and have so far in our hands the fact to which all other facts are relative. From this point of view we may even see a truth in Jacobus dictum as quoted by Sir W. Hamilton: 'Nature conceals God, man reveals God. Nature by itself that is to say is insufficient. The ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge or the mind as known, willing etc. must be treated

as two distinct things. It may be regarded simply as a fact in which case the evolution of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This gives us the science of empirical psychology or as it is now termed psychology *sans phrase*. In order to give an adequate account of its subject matter psychology may require higher or more complex categories than are employed in the other sciences just as biology for example cannot work with mechanical categories alone but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy and hence the establishment of psychology as an independent science has already been alluded to. Since it has been taken up by specialists psychology is being established on a broader basis of induction and with the advantage in some departments of the employment of experimental methods of measurement. But it is not of mind in this aspect that such assertions can be made as those quoted above. Mind as studied by the psychologist—mind as a mere fact or phenomenon—grounds no inference to anything beyond itself. The distinction between mind viewed as a succession of states of consciousness and the further aspect of mind which philosophy considers was very clearly put by Croom Robertson who also made a happy suggestion of two terms to designate the double point of view.

We may view knowledge as mere subjective function but it has its full meaning only as it is taken to represent what we may call objective fact or is such as is named (in different circumstances) real valid true. As mere subjective function which it is to the psychologist it is best spoken of by an unambiguous name and for this there seems none better than *Intellection*. We may then say that psychology is occupied with the natural function of *Intellection* seeking to discover its laws and distinguishing its various modes (perception representative imagination conception etc.) according to the various circumstances in which the laws are found at work. Philosophy on the other hand is theory of *Knowledge* (as that which is known). — Psychology and Philosophy *Mind* (1883) pp 15 16.

The confusion of these two points of view has led and still leads to serious philosophical misconception. It is hardly an exaggeration to say that in the English school since Hume psychology superseded properly philosophical inquiry. And we find even a thinker with a wider horizon like Sir W. Hamilton encouraging the confusion by speaking of psychology or metaphysics while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper with an occasional excursus (as in the theory of perception) into epistemology. The distinction between psychology and theory of knowledge was first clearly made by Kant who repeatedly insisted that the *Critique of Pure Reason* was not to be taken as a psychological inquiry. He defined his problem as the *quid juris* or the question of the validity of knowledge not its *quid facti* or the laws of the empirical genesis and evolution of intellection (to use Croom Robertson's phraseology). Since Kant philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not indeed a preliminary criticism of our faculties or conceptions such as Kant himself proposed to institute in order to determine the limits of their application such a criticism *ab extra* of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent criticism which the conceptions or categories exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explication of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge in the only tenable sense of the term and it lays down in Kantian language the conditions of the possibility of experience. These conditions are the conditions of knowledge as such or as it may be put of objective consciousness—of a self consciousness of a world of objects and through them conscious of itself. The inquiry is therefore, transcendental in its nature and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we pass into the theory of the mind as such

Aesthetics (*q v*) may be treated as a department of psychology or physiology and in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism it is asked are the emotions due which make us declare an object beautiful or sublime? And the question being put in this form the attempt has been made in some cases to explain any peculiarity in the emotions by analysing them into simpler elements such as primitive organic pleasures and prolonged associations of usefulness or fitness. But just as psychology in general cannot do duty for a theory of knowledge so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. Perhaps by talking of "emotions" we tend to give

in unduly subjective colour of the investigation it would be better to speak of the *perception* of the beautiful. Pleasure in it is unqualified and admits no differentiation. In the case of a beautiful object the aesthetic pleasure borrows its specific quality from the presence of determinations essentially objective in the nature though not reducible to the categories of science. Unless indeed we conceive our faculties to be constructed on some arbitrary plan which puts them out of relation to the facts with which they have to deal we have a *prima facie* right to treat beauty as an objective determination of things. The question of aesthetics would then be formulated—What is in things that makes them beautiful and what is the relation of this aspect of the universe to its ultimate nature? That is expounded in metaphysics. The answer constitutes the substance of aesthetics considered as a branch of philosophy. But it is not given simply in abstract terms: the philosophical treatment of aesthetics includes also an exposition of the concrete phases of art as these have appeared in the history of the world relating themselves to different phases of human culture.

Of ethics (*qv*) it may also be said that many of the topics commonly embraced under that title are not strictly philosophical in their nature. They are subjects for a scientific psychology employing the evolutionary method with the conceptions of heredity and development and calling to its aid as such a psychology will do the investigations of all the sociological sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, etc.) and the controversy concerning the freedom of the will belong mainly to psychology. If we exclude such questions in the interest of systematic correctness and seek to determine for ethics a definite subject-matter the science may be said to fall into two departments. The first of these deals with the notion of duty and endeavours to define the good or the ultimate end of action; the second lays out the scheme of concrete duties which are deducible from or which at least are covered by this abstractly stated principle. The second of these departments is really the proper subject-matter of ethics considered as a separate science, but it is often conspicuous by its absence from ethical treatises. However moralists may differ on first principles there seems to be remarkably little practical divergence when they come to lay down the particular laws of morality. It may be added that where a systematic account of duties is actually given the connection of the particular duties with the universal formula is in general more formal than real. It is only under the head of casuistry (*qv*) that ethics has been much cultivated as a separate science. The first department of ethics on the other hand is the branch of the subject in virtue of which ethics forms part of philosophy. As described above it ought rather to be called in Kant's phrase the metaphysics of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysics of personality. The connection of ethics with metaphysics will be patent as a matter of fact if it be remembered how Plato's philosophy is summed up in the idea of the good and how Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connection is also apparent unless we are to suppose that as regards the course of universal nature man is altogether an *imperum in imperio* or rather (to adopt the forcible phrase of Marcus Aurelius) an abscess or excrescence on the nature of things. If on the contrary we must hold that man is essentially related to what the same writer calls a common nature then it is a legitimate corollary that in man as intelligence we ought to find the key of the whole fabric.

**Philosophy of the State, History and Religion.**—In Plato and Aristotle ethics and politics are indissolubly connected. In other words seeing that the highest human good is realizable only in a community the theory of the state as the organ of morality and itself in its structure and institutions the expression of ethical ideas or qualities becomes an integral part of philosophy. The difficulty already hinted at, which individualistic systems of ethics

experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the content of morality is necessarily referred in great part to the experience crystallized in laws and institutions and to the unwritten law of custom, honour and good breeding which has become organic in the society of which we are members. Plato's *Republic* and Hegel's *Philosophie des Rechts* are the most typical examples of a fully developed philosophy of the state, but in the earlier modern period the prolonged discussion of natural rights and the social contract must be regarded as a contribution to such a theory. Moreover if philosophy is to complete its constructive work it must bring the course of human history within its survey and exhibit the sequence of events as an evolution in which the purposive action of reason is traceable. This is the task of the philosophy of history, a peculiarly modern study due to the growth of a humanistic and historical point of view. Lessing's conception of history as an education of the human race is a typical example of this interpretation of the facts and was indeed the precursor which stimulated many more elaborate German theories. The philosophy of history differs it will be observed from the purely scientific or descriptive studies covered by the general title of sociology. Sociology conceives itself as a natural science elucidating a factual sequence. The philosophy of history is essentially teleological, that is to say it seeks to interpret the process as the realization of an immanent end. It may be said therefore to involve a complete metaphysical theory. Social institutions and customs and the different forms of state organization are judged according to the degree in which they promote the realization of the human ideal. History is thus represented by Hegel for example as the realization of the idea of freedom or rather as the reconciliation of individual freedom and the play of cultured interests with the stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements we may claim to possess a philosophy of history. But although the possibility of such a philosophy seems implied in the postulated rationality of the universe many would hold that it remains as yet an unachieved ideal.

There only remains to be briefly noticed the relation of philosophy to theology and the nature of what is called Philosophy of Religion. By theology is commonly understood the systematic presentation of the teaching of some positive or historical religion as to the existence and attributes of a Supreme Being including his relation to the world and especially to man. But these topics have also been treated by philosophers and religious thinkers without dependence on any historical data or special divine revelation under the title of Natural Theology. Natural Theology is specially associated with the Stoic theories of providence in ancient times and with elaborations of the argument from design in the 18th century. But there is no warrant for restricting the term to any special mode of approaching the problems indicated and as these form the central subject of metaphysical inquiry no valid distinction can be drawn between natural theology and general metaphysics. The philosophy of religion on the other hand investigates the nature of the religious consciousness and the value of its pronouncements on human life and man's relation to the ground of things. Unity, reconciliation, peace, joy, the victory that overcometh the world—such in slightly varying phrases is the content of religious faith. Does this consciousness represent an authentic insight into ultimate fact or is it a pitiful illusion of the nerves born of man's hopes and fears and of his fundamental ignorance? The philosophy of religion assumes the first alternative. The function of philosophy in general is the reflective analysis of experience and the religious experience of mankind is *prima facie* entitled to the same consideration as any other form of conscious activity. The certainties of religious faith are matters of feeling or immediate assurance and are expressed in the pictorial language of imagination. It becomes the function of philosophy dealing with these utterances to relate them to the results of other spheres of experience and to determine their real meaning in the more exact terms of thought.

The philosophy of religion also trace in the different theories of the origin of the human mind and the development of the human race. The philosopher of the Middle Ages, who was influenced by the teleological or the physical principles of Aristotle, gave a purely historical and comparative account of the various manifestations of the religious mind without pronouncing on their relative truth or value and without trying to apply the idea of evolution in the philosophy of religion. That idea is fundamental in the philosophy of religion which there are written only from the standpoint of a constructive metaphysical theory.

It is indeed only from the standpoint of such a theory that the definition and divisions of the different philosophical disciplines adopted in this article can be said to hold good. But those who like the positive agnostics and sceptics deny the possibility of ontology as a theory of the ultimate nature of things are still obliged to retain philosophy as a theory of knowledge in order to justify the asserted limitation or impotence of human reason.

(A S P P)

**PHILOSTRATUS, "THE ATHENIAN"** (c. 100–45) the author of the *Life of Apollonius of Tyana* which he dedicated to Julia Domna wife of Alexander Severus and mother of Caracalla (see **APOLLONIUS OF TYANA**). He wrote also *Bioi Sophistōn* (*Lives of the Sophists*), *Gymnasticus* and *Epistolae* (mainly of an erotic character). Very little is known of his career. It is probable that he was born in Lemnos, studied and taught at Athens and then settled in Rome. He is said by Suidas to have been living in the reign of Philip (24–49). The common authorship of *Apollonius* and of the *Lives of the Sophists* is confirmed by internal evidence.

The *Lives* are not in the true sense biographical but rather picturesque impressions of leading representatives. The *Gymnasticus* contains interesting matter concerning the Olympic games and contests. The *Letters* breathe the spirit of the New Comedy and the Alexandrine poets; portions of *Letter 33* are almost literally translated in Ben Jonson's *Song to Celia*. "Drink to me only with thine eyes." The *Hērōikos* formerly attributed to Philostratus the Athenian but probably by another Philostratus (of Lemnos) is a popular disquisition on the heroes of the Trojan War. His other work is the *Ekloges* (*Images*) ostensibly a critical description of 64 pictures in a Neapolitan gallery.

See K. Munscher in *Philologus* (1907) suppl. X, pp. 469–557. Of works bearing the name Philostratus there is a collected edition by C. F. Kayser (Zürich 1844, Leipzig 1870–71) and another by Westermann (Paris 1849) with Latin translation; these supersede those by F. Morel (Paris 1608) and Olearius (Leipzig 1709). There are separate editions of the *Ekloges* by Schenkl and Reisch (Leipzig 1901) of the *Gymnasticus* by Mynas (1858), Daremberg (1858), Voelckmar (Zürich 1862) and especially Julius Juthner (1909) with introd. comments and Ger. trans. of 73 epistles by Boissonade (1842). The *Life of Apollonius* was first published by Aldus (1502); a French translation by Blaise de Vigenère appeared in 1596; an Eng. trans. of bks. 1 and II was published (1680) by C. Blount with notes by Lord Herbert of Chesham (prohibited in England in 1693; it was reprinted on the Continent); a full translation appeared in 1903. Critical works on the *Ekloges* are numerous: K. Friederichs *Die Philostratischen Bilder* (1860), Goethe *Philostrats Gemälde in Complete Works* (ed. Stuttgart 1879), Brunn *Die Philostratischen Bilder* (1860), A. Bougot *Une Galerie antique* (1881), E. Bertrand *Un Critique d'art dans l'antiquité: Philstrate et son école* (1882), Bergk *Die Philstrate in Fünf Abhandlungen zur Geschichte der griechischen Philosophie und Astronomie* (1883), Schmid *Atticismus* IV 7 on the attribution of the works and Überweg *Grundriss der Gesch. der Philosophie* Bd I (1926).

**PHILOXENUS**, of Cythera (435–380 B.C.) Greek dithyrambic poet. On the conquest of the island by the Athenians he was taken as a prisoner of war to Athens where he was purchased by the dithyrambic poet Melanippides who educated him and set him free. Philoxenus afterwards resided in Sicily at the

court of Dionysius, the tyrant of Syracuse whose bad verse he imitated. Philoxenus was in consequence sent to work in the quarries. After a time he was recalled in Greece. I. K. and A. Reisinger (1901) and (ed.) E. 1951. According to S. I. Philoxenus composed a dithyramb and a lyric poem on the conquest of the Argives. In his hand the dithyramb was to be performed for the first time and the music composed by Philoxenus. He is also credited with the Cyclops for the first Greek writer on the subject upon Dionysius who is a novel or parody of the Cyclops. It was parodied by Aristophanes in the *Ptarmakos*. The popularity of Philoxenus is attested by a monumentary record of his works by the Athenians in 471 B.C.

F. Lamm with I. K. G. Lippat (84) T. Berol. *Poetae Graeci* 1911.

**PHILOXENUS** (Syriac: Aksenaya) (fl. c. 500) of Mabbog, one of the best Syriac prose writers and a vehement champion of Monophysite doctrine. He was by birth a Persian born at Tahal in the district of Beh Garmir east of the Tigris. He was educated at Edessa. Philoxenus attracted notice by his strenuous advocacy of Monophysite doctrine and on the expulsion of Calandio (the orthodox patriarch of Antioch) in 485 was ordained bishop of Mabbog (Hierapolis) by his Monophysite successor Peter the Father (Barhebraeus *Chron. eccl.* 183). It was probably during the earlier years of his episcopate that Philoxenus composed his thirteen homilies on the Christian life. Later he revised the Syriac version of the Bible and with the help of his chorepiscopus Polycarp produced in 508 the so-called Philoxenian version used by the Monophysites during the 6th century. He bitterly opposed Flavian II who had accepted the decrees of the Council of Chalcedon and was patriarch of Antioch from 498 to 511. In 511 the Monophysites finally ousted and replaced him by their partisan Severus. But Justin I who succeeded Anastasius in 518 was less favourable to Severus and Philoxenus and in 519 they were sentenced to banishment. Philoxenus was sent to Philipopolis in Thrace and afterwards to Gangra in Paphlagonia where he met his death by foul play in 533.

Of the chief monument of his scholarship—the Philoxenian version of the Bible—only the Gospels and certain portions of Isaiah are known to survive (see Wright *Syr. Lit.* 14). His thirteen homilies on the Christian life and character have been edited and translated by Budge (London 1894). Many of his letters survive.

**PHIPS** or **PHIPPS**, **SIR WILLIAM** (1651–1695) colonial governor of Massachusetts was born on Feb. 1651 at Woolwich Me. near the mouth of the Kennebec river. He was a shepherd until he was 18 and then a ship carpenter's apprentice for four years, worked at his trade in Boston for a year at this time learning to read and write. In 1687 with a commission from the British Crown he found after a search of many years a wrecked Spanish treasure ship of which he had heard on a voyage to the Bahamas. From it he recovered £300,000 of which he received £16,000 as his share. He was knighted by James II and was appointed sheriff of New England. Poorly educated and ignorant of law Phips could accomplish little and returned to England. In 1689 he returned to Massachusetts and at once entered into the life of the colony. He was soon appointed commander of an expedition against the French in Canada which sailed in April 1690 and easily captured Port Royal. A much larger expedition led by Phips in July against Quebec and Montreal ended disastrously. In the winter of 1690 he returned to England and urged with Increase Mather the colonial agent a restoration of the colony's charter annulled during the reign of Charles II. The Crown at the suggestion of Mather appointed him the first royal governor under the new charter. On reaching Boston in May 1692 Phips found the colony in a very disordered condition and though honest and persevering he was unfitted for the difficult position. In defending the frontier he displayed great energy but his policy of building forts was expensive and therefore unpopular. Numerous complaints to the home government resulted in his being summoned to England to answer charges. While in London awaiting trial he died on Feb. 18 1695.

See Cotton Mather's *Life of His Excellency Sir William Phips*.

[illegible]

This is the story of the life of the great Athenian statesman, Pericles, who was the leader of the Athenian people during the time of the Peloponnesian War. He was a man of great ability and courage, and he was the first to introduce the system of democracy into Athens. He was also a great orator, and he was the first to introduce the system of public education into Athens. He was the first to introduce the system of public works into Athens, and he was the first to introduce the system of public health into Athens. He was the first to introduce the system of public safety into Athens, and he was the first to introduce the system of public order into Athens. He was the first to introduce the system of public justice into Athens, and he was the first to introduce the system of public morality into Athens. He was the first to introduce the system of public religion into Athens, and he was the first to introduce the system of public art into Athens. He was the first to introduce the system of public science into Athens, and he was the first to introduce the system of public philosophy into Athens. He was the first to introduce the system of public literature into Athens, and he was the first to introduce the system of public history into Athens. He was the first to introduce the system of public law into Athens, and he was the first to introduce the system of public government into Athens. He was the first to introduce the system of public justice into Athens, and he was the first to introduce the system of public morality into Athens. He was the first to introduce the system of public religion into Athens, and he was the first to introduce the system of public art into Athens. He was the first to introduce the system of public science into Athens, and he was the first to introduce the system of public philosophy into Athens. He was the first to introduce the system of public literature into Athens, and he was the first to introduce the system of public history into Athens. He was the first to introduce the system of public law into Athens, and he was the first to introduce the system of public government into Athens.

**PHOCIS**, an ancient district of central Greece (now a department pop. 65,000 area 6 sq m) bounded on the W. by Ozolian Locris and Doris on the N. by Opuntian Locris on the E. by Boeotia and on the S. by the Corinthian Gulf. The main ridge of Iarnia (3068 ft.) traverses the heart of the country. Between this and the northern frontier range of Cnemis (3000 ft.) is the narrow fertile valley of the Cephissus along which lie most of the Phocian towns. South of Perrina are the two small plains of Crissa and Anticyra separated by Mt. Cirphus. Phocis was mainly pastoral.

Its early history is obscure. Its population was reckoned Aeolic but the dialects are of the West Greek group more akin to Doric. There was a tradition that the Phocians once owned land round Diphnus opposite Euboea and had their frontier at Thermopylae. Later restriction of territory was due to the hostility of Boeotia and Thessaly. The latter in the 6th century even raided the Cephissus valley. In early days Phocians controlled the sanctuary of Delphi. But Delphi constantly strove for independence and about 590 B.C. induced a coalition of Greek states to proclaim a Sacred War and free the oracle from Phocian supervision. Thus Phocian influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence but their irresolute conduct lost Thermopylae for the Greeks and at Plataea they were on the Persian side. In 457 an attempt to control the head waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the metropolis of the Dorians. A similar attack on Delphi in 448 was again frustrated by Sparta but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians with whom they became allied in 454. When Athenian land power declined Phocian friendship waned and in the Peloponnesian War Phocis was nominally an ally of Sparta and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by Bœotian oppression. After helping Sparta to invade Bœotia during the Corinthian War (395-394) the Phocians received assistance from Sparta in 380 but afterwards submitted to the growing power of Thebes. Phocians took part in Epameinondas' earlier invasions into the Peloponnese but abstained from the campaign of Mantinea (370-362). In return for this negligence the Thebans secured a penal decree against them for religious offences from the Amphictyonic synod (356). The Phocians led by two capable generals, Philomelus and Onomarchus, replied by seizing Delphi and using its riches to hire mercenaries with whose help they invaded Bœotia and Thessaly, and though driven out of Thessaly

**PHOCYLIDES**, Greek  $\phi\omicron\kappa\upsilon\lambda\iota\delta\epsilon\varsigma$  = Milk and comfort-  
giver of Theodorus was born c. 100 BC. A few fragments of  
his  $\lambda\iota\mu\eta\eta$  have been preserved, chiefly in the *Florilegium* of  
Stobaeus. A complete didactic poem called *Ποιηματα νοσητικων*  
or *pharmaka* and which bear the name of Phocylides is now con-  
sidered to be the work of an Alexandrian Christian or Jewish  
origin who lived between c. 100 and A.D. 50.

**PHOEBE** (*Say's phoebe*) the name given to a familiar American bird belonging to the family *Tyrannidae* (the American flycatchers). Distinguished by its dark crown cap olive grey plumage and the white outer vane to the outer tail feather. The phoebe breeds in eastern North America from the south west Mackenzie southward wintering in southern U.S.A. and Mexico. The bulky nest of moss and mud lined with grass hair and feathers is placed on a beam or under a bridge or bank often close to or on a building. Say's phoebe (*S. sayi*) is a more westerly species abundant west of Kansas and Nebraska. The black phoebe (*S. nigricans*) has a more southern range.

**PHOEBUS**, a common epithet of Apollo (*q v*)

**PHOENICIA**, in ancient geography the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el Kebir) in the north to Mt Carmel in the south a distance of rather more than two degrees of latitude. These limits however were exceeded at various times thus north of the Eleutherus lay Aradus and Marathus and south of Carmel the border sometimes included Dor and even Joppa. The harbours which played so important a part in antiquity are nearly all silted up and with the exception of Beirut afford no safe anchorage for the large vessels of modern times. Sidon Tyre and Aradus though now connected with the mainland were built originally upon islands the Phoenicians preferred such sites because they were convenient for shipping and easily defended against attack.

The chief towns of ancient Phoenicia as we know of them from the Amarna tablets (15th century B.C.) and from Egyptian Assyrian and the Old Testament documents were the following Acco (now Acre or Akko Judg. i. 31) Achzib (now ez Zīb *ibid.*) Ahlab (in Assyrian Mahalliba *ibid.*)—three towns on the coast south of Tyre Kanah (Josh. xix. 28) Tyre (Phoen. Sor now Sur) Zarephath or Sarepta (1 Kings xvii. 9 [now Sarafand]) Sidon (now Šaida) Berytus (Biruta in Egyptian Biruna in the Amarna tablets now Beirut) Byblus (in Phoen. and Hebr. Gebal now Jebeil) Arka 80 m. north of Sidon (Gen. x. 17 now Arka) Sin (Assyr. Siannu *ibid.*) Sumyra (Gen. x. 18 now Šumra) Marathus (now Amrit) not important till the Macedonian period Arvad or Aradus (in Phoen. Arwad now Ruad Gen. x. 18, Ezek. xxvii. 8-11) the most northerly of the great Phoenician towns

**Race and Language.**—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. The Phoenicians themselves believed that they had migrated from an eastern shore probably meaning Babylonia.

By settling along the Syrian coast they developed a strong Semitic language which differed from other Canaanite dialects. They called themselves Canaanites and their land Canaan, but their name in the Amarna tablets is *ʿAḥḥi* and with this we see the term *ʿAḥḥi* of Hecataeus (*Fr Hist* 1.1.1) the Phoenicia was formerly called *ʿAḥḥi* (*Chuz*) a name which Philo of Byblos adopts into his mythology by which Canaan who was afterward called Phoenix the eponym of the Phoenicians (*Fr Hist* 1.1.369). In the reign of Antiochus IV and his successors the coin of Laodicea or Libanus bear the legend *Of Laodicea* which is in Canaan (*Coolidge North Semitic Inscriptions* quoted a *NSI* No 149 B 5) the Old Testament also sometimes denotes Phoenicia and Phoenicians by Canaan and Canaanites (*Isa* xlii 11 *Obad* 1 *Zeph* 1 11) though the latter names generally have a more extended sense. But Sidonians is the usual designation both in the Old Testament and in the Assyrian monuments (*Sidonnu*) and even at the time of Tyre's greatest ascendancy we read of Sidonians and not Tyrians in the Old Testament and in Homer thus Ethbaal king of Tyre (*Jos* i 31) is called king of the Sidonians in 1 Kings xvi 31. In the Homeric poems we meet with *Sidonoi* *Sidone* (*Od* iv 618 *Il* vi 90 *Od* xiii 85 *Il* vi 291) and *Phoinikes* *Phoinike* (*Od* xiii 1 xiv 88 *seq* etc) and both terms together (*Od* iv 85 *seq* *Il* xxiii 74 *seq*). And the Phoenicians themselves used Sidonians as a general name thus in one of the oldest Phoenician inscriptions (*CIS* 1 5 = *NSI* No 11) Hiram II king of Tyre in the 9th century is styled king of the Sidonians. But among the Greeks Phoenicians was the name most in use *Phoinikes* (plur of *Phoinix*) for the people and *Phoinike* for the land (*cf* PHOENIX). The former was probably the older word and may be traced to *phoinos* = blood red the Canaanite sailors were spoken of as the red men on account of their sunburnt skin.

**Language**—Inscriptions coins topographical names preserved by Greek and Latin writers names of persons and the Punic passages in the *Poenulus* of Plautus all show conclusively that the Phoenician language belonged to the North Semitic group and to that subdivision of it which is called the Canaanite and includes Hebrew and the dialect of Moab. A comparison between Phoenician and Hebrew reveals close resemblances both in grammatical forms and in vocabulary in some respects older features have been preserved in Phoenician others are later others again are peculiar to the dialect many words poetic or rare or late in Hebrew are common in Phoenician. Hence we may conclude that the two languages developed independently from a common ancestor which can be no other than the ancient Canaanite of which a few words have survived in the Canaanite glosses to the Amarna tablets (written in Babylonian). But in forming an estimate of the Phoenician language it must be remembered that our material is scanty and limited in range the Phoenicians were in no sense a literary people moreover except the inscriptions found at Gebal now Jebel (10th century) and *NSI* No 11 most of the inscriptions are subsequent to the 6th century B.C. the majority belong to the 4th century and later by which time the language must have undergone a certain amount of decay. Indirectly however the Phoenicians rendered one great service to literature they took a large share in the development and diffusion of the alphabet which forms the foundation of Greek (*Herod* v 58) and of all European writing. The Phoenician letters in their earlier types are practically identical with those used by the Hebrews the Moabites and the Aramaeans of north Syria (*NSI* Plates xii xiii). They passed through various modifications in the course of time after leaving the mother country the script acquires a more cursive flowing style on the stones from Cyprus and Attica the tendency becomes more strongly marked at the Punic stage until in the neo Punic from the destruction of Carthage (146 B.C.) to the 1st century A.D. both the writing and the language reached their most degenerate form. As a rustic dialect the language lasted in north Africa till the 5th century A.D. In his sermons St Augustine frequently quotes Punic words. The oldest specimens of Phoenician writing at

present known have been found at Gebal. In 1922 Montet unearthed the sarcophagus of Ahiram incised with a Phoenician inscription in an archaic form of lettering which bears a close resemblance to the inscription of Abi baal discovered some years ago on the same site.

**History**—The Phoenicians in imitation of the Egyptians claimed that their oldest cities had been founded in remote antiquity but no certainty can be attached to the traditional chronologies of Herod ii 44 Justin xviii 5 Menander in *Jos* i 31 viii 5 i and c 4p 1 18.

Phoenicia comes into history proper c 1600 B.C. when the Egyptian empire began to extend in the direction of Asia under Ahmosi (Ama) I who carried his arms into Syria and conquered at least part of it and Phoenicia the latter being the country called *Da hu* on the Egyptian monuments (*Müller As u Eur* p 181). Thothmes III (1505-1449) repeated and consolidated the earlier conquest and established Egyptian suzerainty over all the petty states of Syria and Phoenicia (*see* EGYPT History I). For the geography and civilization of Canaan about 1400 B.C. we have valuable evidence in the Egyptian papyrus Anastasi I which mentions Kepuna (Gubna Gebal Byblos) the holy city and continues Come then to Berytus to Sidon to Sarepta. Where is the ford of Natana (? Nahr el Kasimiyeh or a town)? Where is Eutu (? Ushu Palaetyrus)? Another city on the sea is called a haven Dar (Tyre) is its name water is carried to it in boats it is richer in fish than in sands. But the fullest information about the state of Phoenicia in the 15th and 14th centuries B.C. comes from the Amarna tablets among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh. It was a time of much political disturbance. The Hittites (*q.v.*) were invading Syria nomads from the desert supported the invasion and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were divided. Aradus Simyra Sidon supported the rebellion Rib addi the regent of Byblos and Abi melech king of Tyre held out for Egypt but while all the towns made professions of fidelity they were scheming for their own interests and in the end Egypt lost them all except Byblos. The tablets which reveal this state of affairs are written in the language and script of Babylonia and thus show indirectly the extent to which Babylonian culture had penetrated Palestine and Phoenicia at the same time they illustrate the closeness of the relations between the Canaanite towns and the dominant power of Egypt. After the reign of Amenophis IV (1376-66) that power collapsed altogether but his successors attempted to recover it and Ramses (Rameses) II reconquered Phoenicia as far as Beirut and carved three tablets on the rock beside the Nahr el Kelb (*Gressmann Texte u Bilder* 11 Pl lxx). In the reign of Ramses III (c 1200) many great changes began to occur owing to the invasion of Syria by peoples from Asia Minor and Europe which ended in the establishment of the Philistines on the coast near Ashkelon. The successors of Ramses III lost their hold over Canaan the 21st dynasty no longer intervened in the affairs of Syria but Sheshonk (Shishak) the founder of the 22nd dynasty about 928 B.C. endeavoured to assert the ancient supremacy of Egypt (*cf* 1 Kings xiv 25 *sqq.*) but his successes were not lasting and as we learn from the Old Testament the power of Egypt became henceforward ineffective.

**Independence of Phoenicia**—Between the withdrawal of the Egyptian rule in Syria and the western advance of Assyria there comes an interval during which the city states of Phoenicia owned no suzerain. Gebal had kings of its own Ahiram Ithobaal Abi baal in the 10th century as recent excavations have shown. The history of this period is mainly a history of Tyre, which not only rose to a sort of hegemony among the Phoenician states but founded colonies beyond the seas (p 769). From 970 to 772 B.C. the bare outline of events is supplied by extracts from two Hellenistic historians Menander of Ephesus and Diodorus (largely dependent upon Menander) which have been preserved by Josephus *Ant* viii 5 3 and c 4p 1 17 18. From the data given in these passages we learn that Hiram I son of Abi baal reigned in Tyre from 970 to 936 B.C. The Tyrian annals more

none in connection with the [redacted] and [redacted] car,  
before he left the [redacted] District [redacted] (Ch. 10)  
of [redacted] and [redacted] [redacted] [redacted] [redacted]

**Constitution**—At the point I refer it to mention what I have known about the constitution of the Phoenician state. All Carthaginians paid to him and a council of 100 members. In the name of the chief of the city in Phoenicia itself and in Cyprus is called king. The royal houses claimed divine descent and the king could not be chosen outside his men. His power however was limited by the wealthy merchant families who possessed great influence in public affairs. The priests of Melkarth at Tyre was the second man in the kingdom. Associated with the prince was a council of elders such was the case at Gebal (Byblus) from the earliest times to the latest (Ezek xxxiii 9) at Sidon this council consisted of 100 members (Diod xvi 45) perhaps also at Tyre (VSI p 19). Incriptions of the 3rd and 2nd centuries B.C. mention a *Rab* (chief) in Sidon Cyprus and Gaus (Gozo) what his position was it is difficult to say in the colonies he may have been a district governor. During Nebuchadrezzar's time as we have seen a republic took the place of the monarchy at Tyre and the government was administered by a succession of suffetes (judges) they held office for short terms and in one instance two ruled together for six years. Much later in the 3rd century B.C. an inscription from Tyre mentions a suffete (VSI No 8) without adding more to our knowledge. Carthage of course was governed by two suffetes and these officers are frequently named in connection with the Carthaginian colonies (VSI p 113 seq) but we must be careful not to draw the inference that Phoenicia itself had any such magistracies. Under the Persians a federal bond was formed comprising Sidon Tyre and Aradus whose duty it was to contribute 300 triremes to the Persian fleet (Herod vii 89) the lesser towns being under the command of the great cities. But federation on a larger scale was never possible in Phoenicia for the reason that no sense of political unity existed to bind the different states to each other. Commercial interests dominated everything else and while these stimulated a municipal life not without vigour civil discipline and loyalty were but feebly felt. On occasion the towns could defend their independence with strenuous courage the higher qualities which make for a progressive national life the Phoenicians did not possess.

**The Persian Period 538-333 B C** —Phoenicia now became part of the fifth satrapy of the Persian empire and entered upon a spell of comparative peace and growing prosperity At this period Sidon occupied the position of leading state in the fleet her king ranked next to Xerxes and before the king of Tyre (Herod viii 67) her situation afforded advantages for expansion which Tyre on its small and densely populated island could not rival In the first half of the 4th century Straton I (in Phoen. *Abd asharti* or *Bod asharti*) was king c 374-362 He cultivated friendly relations with Athens indicated in a decree of *proxenia* (Michel *Rec dmscr gr* No 93=*CI G* No 87) and the extent to which phil Hellenic tendencies prevailed at this time in Sidon is shown by the royal sarcophagi noble specimens of Greek art which have been excavated in the necropolis of the city It was in the reign of Straton that Tyre fell into the hands of Evagoras king of Salamis who had already supplanted Phoenician with Greek civilization in Cyprus (Isocr *Evag* 62 *Paneg* 161 *Diod* xv 2) Straton made friends with Nicocles son of Evagoras and with him came to an untimely end through their implication in the great revolt of the satraps 362 B C A new revolt of Sidon against the Persians took place under King Tennes with the aid of Nectanebus of Egypt, the Sidonians carried the rest of Phoenicia with them and drove the satraps of Syria and Cilicia out of the country Tennes however, betrayed his people and opened the city to Artaxerxes III, then he was executed after he had served the ends of the great king (346 B C. *Diod.* xvi 41-45) The last king of Sidon was Straton II (*Abd-ashtart*, 346-332) before the Persian empire came to an end.

Towards the close of the 5th century the Phoenician coins begin to supplement our historical sources. From the time of

Dr. J. H. D. ... and vassal ... Hence ... of their own ... as a ... with the ... the names ... and ... from the ... difficult to obtain much information. The native inscriptions however have borne a little fruit. Only one has been discovered in Phoenicia itself. One of the earliest of these is the inscription of Lyblu (CIS 111=VSI No 3) dating from the Persian period. It records a dedication made by Yehawmilk king of Gebal and mentions the name of the king's grandfather Uri milk, but the exact dates of their reign are not given.

**The Macedonian Period 33-69 B.C.—**When Alexander the Great entered Phoenicia after the battle of Issus (333 B.C.) the kings were absent with the Persian fleet in the Aegean but the cities of Aradus, Byblos and Sidon welcomed him readily, he last named showing special zeal against Persia. The Tyrians also offered submission but refused to allow the conqueror to enter the city and sacrifice to the Tyrian Hercules. Alexander was determined to make an example of the first who should offer opposition and at once began the siege. It lasted seven months. With enormous toil the king drove out a mole from the mainland to the island and thus brought up his engines, ships from the other Phoenician towns and from Cyprus lent him their aid and the town at length was forced in July 333. 8,000 Tyrians were slain, 50,000 sold as slaves and only a few notables, the king Azemilko and the festival envoys from Carthage who had taken refuge in the sanctuary of Melkarth were spared (Diod. xvii. 40-46). It is not unlikely that Zech. ix. 2-4 refers to this famous siege. For the time Tyre lost its political existence while the foundation of Alexandria presently changed the lines of trade and dealt a blow even more fatal to the Phoenician cities.

During the wars of Alexander's successors Phoenicia changed hands several times between the Egyptian and the Syrian kings. From the year 25 the people of Tyre reckoned their era (*CIS* 17=*NSI* No 9 cf 10). The Tyrian coins of the period stamped with native Greek and Egyptian symbols illustrate the traditional relations of the city and the range of her ambitions. A special interest attaches to these silver tetradrachms and didrachms because they were used by the Jews for the payment of the temple tax as shekels of the sanctuary (*NSI* pp 351-44).

Among the Phoenician states we know most about Sidon during this period. The kingship was continued for a long time. The story goes that Alexander raised to the throne a member of the royal family Abdalonymus who was living in obscure poverty and working as a gardener (Justin xi 10 Curt iv 1 Diod xvii 47 wrongly connecting the story with Tyre). In 312 Ptolemy then master of Phoenicia appointed his general Philocles king of the Sidonians and a decree in honour of this king has been found at Athens (Michel No 387 cf 1261) but he cannot have reigned long. For at the end of the 4th and the beginning of the 3rd century we have evidence of a native dynasty in the important inscriptions of Tabnith Eshmunazar and Bodashtart and in the series of inscriptions (repeating the same text) discovered at Bostan esh Shekh near Sidon (NSI Nos 4 5 6 and App 1). With Bodashtart so far as we know the dynasty came to an end say about 250 B.C.

After the death of Antiochus IV Epiphanes in 164 B C the kingdom of the Seleucids began to collapse Berytus was destroyed by the usurper Trypho in 140 B C Tyre in 120 and Sidon in 111 received complete independence and inaugurated new eras from these dates Byblus and Tripolis fell into the hands of "tyrants" (Strabo xvi 2 18 Jos *Ant* xiv 3 2) from 83-69 B C the entire kingdom was held by the Armenian Tigranes

**Roman Rule.**—At last in 64 B.C. Pompey arrived upon the scene and established order out of chaos. Phoenicia was incorporated into the Roman province of Syria. Aradus, Sidon, Tyre and Tripolis were confirmed in their rights of self-government and in

[illegible]

**Navigation Trade Colonies**—The Phoenicians were essentially a seafaring nation. Fearful and patient navigators they ventured into oceans where no one else dared to go and always with next to other monopoly they carefully guarded the secrets of their route to sea and discovery and their knowledge of winds and currents. At the beginning of the 5th century B.C. a Phoenician fleet is said to have circumnavigated Africa (Herod iv 42). In the great power Phoenician ship and sailors were indispensable. Hannibal, I Armetichus and Necho Xerxes Alexander all in turn employed them for their transports and sea-fight. Even when Athens had developed a rival navy Greek observers noted with admiration the discipline kept on board the Phoenician ships and the skill with which they were handled (Xen. Oec vi). All the Phoenician vessels from the round merchant boat (*γαλῆος*—after which the island of Gauls now (1870) near Marseilles was called) to the great Tarshish ships the

East Indian of the ancient world excelled those of the Greek in speed and equipment. As E. Meyer points out the war between Crete and the Persians was mainly a contest between the seapowers of Greece and Phoenicia. At what period did Phoenicia first rise to be a power in the Mediterranean? We are gradually approaching a solution of this obscure problem. Recent discoveries in Crete (qv) have brought to light the existence of a Cretan or Minoan sea power of remote antiquity and it is clear that a great deal of what used to be described as Phoenician must receive quite a different designation. The Minoan sea power was at last broken up by invaders from the north and a Carian rule became dominant in the Aegean (Herod. i. 171; Thucyd. i. 4-8). It was a time of disorder and conflict due to the immigration of new races into the ancient seats of civilization and synchronized with the weakening of the power of Egypt in the countries which bordered on the eastern Mediterranean. This was in the 12th century B.C. The Tyrian trader saw that his opportunity was come and the Aegean lay open to his merchant vessels. Where much is still obscure, all that seems certain is that the antiquity of Phoenicia as a sea and trading power has been greatly exaggerated both in ancient and in modern times. The Minoan power of Cnossus preceded it by many centuries, the influence of Phoenicia in the Aegean cannot be carried back much earlier than the 12th century B.C.

A vivid description of the Phoenicians trade at the time of Tyre's prosperity is given by Ezekiel (xxvii 12-25) and it shows how extensive were their commercial relations not only by sea but by land as well. It was they who distributed to the rest of the world the wares of Egypt and Babylonia (Herod i 1). From the lands of the Euphrates and Tigris regular trade routes led to the Mediterranean with trading stations on the way several of which are mentioned by Ezekiel (xxvii 23). In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the 22nd and 23rd dynasties (825-650 B.C.) when all other foreign merchants were frightened away. Though there were never any regular colonies of Phoenicians in Egypt the Tyrians had a quarter of their own in Memphis (Herod ii 112). The Arabian caravan trade in perfume, spices and incense passed through Phoenician hands on its way to Greece and the west (Herod, iii, 107). Between Israel and Phoenicia the relations naturally

re not he to her provided art in need same of life and  
 re enough to meet of luxur and plendur (Ezek xxvii  
 12) I read he to have sold the home pun to Phoenician

 ρπος σπιος μα παλλαις βελιλος* Another article of  
 commerce which the Phoenician brought to the market was  
 amber

The Phoenician colonies were all supposed to have been founded from Tyre with regard to the colonies in Cyprus and north Africa this was undoubtedly true Cyprus possessed resources of timber and copper which could not fail to tempt the keen eyed traders across the water who made Cition (from Kittim the name of the original non-Semitic immigrant) their chief settlement and there established themselves in Idalion Tamassus Lapethus Larnika Oirphadasat (Karti hadasti) and other towns. In the incursions of the 4th to 3rd centuries the Phoenician potentates in the island call them selves kings of Kition and Idalion (VSI pp 35-39)

Homos represents the Ithomians as present in Greek waters for purposes of traffic but not as settlers (*Il* xxiii, 44). They occupied trading stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex of which an enormous supply was needed for the dyeing industry. specially famous was the purple of the Laconian waters, the isles of Elishah of Ezek. xxvii, 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Greek world the Phoenicians made themselves heartily detested by their passion for gain (*Plato Rep.* iv, 436 A).

Farther west in the Mediterranean Phoenician settlements were planted first in Sicily at Heraclea or Ras Melqarth the islands between Sicily and Africa Melita (Malta) on account of its valuable harbour Gulus and Cossura were also occupied (Diod v 12) and a beginning was made with the colonization of Sardinia and Corsica but farther west still more permanent colonies were established It was the trade with Tarshish *ie* the region of Tartessus in south west Spain which contributed most to the Phoenicians wealth it was said that even the anchors of ships returning from Spain were made of silver (Diod v 35) From Gadir (Punic *Gader* Lat *Gades* now Cadiz) the Sidonian ships ventured farther on the ocean and drew tin from the mines of north west Spain or from the richer deposits in the Cassiterides *ie* the Tin Islands These were discovered to be not a part of Britain as was imagined at first but a separate group by themselves now known as the Scillies hence it is improbable that the Phoenicians ever worked the tin mines in Cornwall

The rich trade with Spain led to the colonization of the West. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (1300 B.C.) in the period of Tyre's first expansion. Luxus in Mauretania, Gades and Utica are said to have been founded one after the other as far back as the 12th century B.C. Most of the African colonies were no doubt younger, we have traditional dates for Aozia (887-855) and Carthage (813). A large part of north west Africa was colonized from Phoenicia, owing to these first settlers and after them to the Carthaginians, the Phoenician language became the prevailing one and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies which, unlike those of Greece, remained subject to the mother city and paid tithes of their revenues to its chief god, Melqarth and sent envoys annually to his feast. Then at the beginning of the 8th century B.C. the colonial power of Tyre began to decline, on the mainland and in Cyprus the Assyrians

g in d t e upper hand n he Gre k islands the Phoenician nad already been displaced o a ret ver by h d ancing ide of Dori n coloni tion Ba Tyre dec cu in power he colonies tu ned more and more to Carthage a heir nat ral paren and prot cts For effective control over a colonial empire C rthage had the ad an age of si uation over far away Tyre the traditional bonds grev l and th an sent dues ceased to be p id thou h as late as the middle of the 6th century Carthage rendered tithes to the Tyrian Meqarth And the nothe country cherished it claim s long after they had lost realty in the nd century B C for example Sidon stamped her coins with the legend Mother of Kambe (ie Carthage) Hippo Kition Tyre (VSI p 33)

**Manufactures Inventions Art**—From an early date the towns of the Phoenician coast were occupied not only with distributing the merchandise of other countries but with working at industries of their own especially purple dyeing and textile fabrics (*Il* vi 289 sqq) metal work in silver gold and electrum (*Il* xxiii 141 sqq *Od* iv 615 sqq xv 458 sqq) and glass work which had its seat at Sidon The iron and copper mines of Cyprus (not Sidon as Homer implies *Od* xv 44) furnished the ore which was manufactured into articles of commerce Egyptian monuments frequently mention the vessels of gold and silver iron and copper made by the Dahi ie the Phoenicians (W M Muller *As u Eur* 306) and in Cyprus and at Nimrud bronze and silver paterae have been found engraved with Egyptian designs the work of Phoenician artists (see table cases C and D in the Nimrud gallery of the Brit Mus) The invention of the e various arts and industries was popularly ascribed to the Phoenicians no doubt merely because Phoenician traders brought the products into the market But dyeing and embroidery probably came from Babylon in the first instance glass making seems to have been borrowed from Egypt the invention of arithmetic and of weights and measures must be laid to the credit of the Babylonians The ancients believed that the Phoenicians invented the use of the alphabet (eg Pliny *NH* v 13 cf vii 5, Lucian *Bell Crv* iii 20 seq) but it is unlikely that any genuine tradition on the subject existed and though the Phoenician theory has found favour in modern times it is open to much question

The art of Phoenicia is characterized generally by its dependence upon the art of the neighbouring races It struck out no original line of its own and borrowed freely from foreign especially Egyptian models Remains of sculpture engraved bronzes and gems show clearly the source to which the Phoenician artists went for inspiration for example the uraeus frieze and the winged disc the *ankh* or symbol of life are Egyptian designs frequently imitated It was in the times of the Persian monarchy that Phoenician art reached its highest development and to this period belong the oldest sculptures and coins that have come down to us A characteristic specimen of the former is the stele of Yehaw milk king of Gebal (*CIS* i 1) in which the king is represented in Persian dress and the goddess to whom he is offering a bowl looks exactly like an Egyptian Isis Hathor (Gressmann *Texte u Bilder* 2 ii Pl ccviii) The whole artistic movement in Phoenicia may be divided into two great periods in the first from the earliest times to the 4th century B C Egyptian influence and then Babylonian or Asiatic influence is predominant but the national element is strongly marked while in the second Greek influence has obtained the mastery and the native element though making itself felt is much less obtrusive Throughout these periods works of art such as statues of the gods and sarcophagi were imported direct at first from Egypt and afterwards mainly from Rhodes The finest sarcophagi that have been found in the necropolis of Sidon (now in the Imperial Museum Constantinople) are not Phoenician at all but exquisite specimens of Greek art The Phoenicians spent much care on their burial places which have furnished the most important monuments left to us Thus on the site of Gebal now Jebel the French excavators under the leadership of Montet, 1921-23 have unearthed the fine sarcophagus of Ahiram, Egyptian in style, and engraved with the earliest Phoenician inscription so far known,

Gressmann *Texte u Bilder* i 440 ii 9-13 and *Il* cliv (19) Besides bronzes and statues which belong as a rule to the Greek period the most characteristic objects usually found are earthen pitcher and lamp, lavae, cense and gems Of buildings which can be called architectural specimens now exist on Phoenician soil for the most part but for a few the inhabitants have used the ruins as convenient quarries Not a vestige remains of the great sanctuary of Melqarth at Tyre a few traces of the temple of Adon near Byblus were discovered by Renan and a peculiar mausoleum Buja al Bezzaq is still to be seen near Amrit excavation at Boan el Sheikh near Sidon revealed parts of the enclosure or foundations of the temple of Eshmun (VSI p 401) the conduits of Ras el Ain south of Tyre are considered to be of ancient date

**Religion**—Like the Canaanite of whom they formed a branch the Phoenician connected their religion with the great powers and processes of nature The god whom they worshipped belonged essentially to the earth the fertile field trees and mountains headlands and rivers and springs were believed to be inhabited by different divinities who were therefore primarily local many in number with no one in particular supreme over the rest It seems however that as time went on some of them acquired a more extended character thus Baal and Astarte assumed celestial attributes in addition to their earthly ones and the Tyrian Melqarth combined a celestial with a marine aspect The gods in general were called *elonim elim* Plautus uses *alonum alonuth* for gods and goddesses (*Poen* v I 1) These plurals go back to the singular form El the common Semitic name for God but neither the singular nor the plural is at all common in the inscriptions (VSI pp 24 41 51) El by itself has been found only once the fem Elath is also rare (*ibid* pp 135 158) The god or goddess was generally called the Baal or Baalath of such and such a place a title which was used not only by the Canaanites but by the Aramaeans (Be el) and Babylonians (Bel) as well There was no one particular god called Baal the word is not a proper name but an appellative a description of the deity as *owner* or *mistress* and the same is the case with Milk or Melek Adon Amma which mean *king lord mother* The god himself was unnamed or had no name Occasionally we know what the name was the Baal of Tyre was Melqarth which again means merely king of the city similarly among the Aramaeans the Baal of Harran was the moon god Sin As each city or district had its own Baal the husband of the land which he fertilized so there were many Baals and the Old Testament writers could allude to the Baalim of the neighbouring Canaanites Sometimes the god received a distinguishing attribute which indicates an association not with any particular place but with some special characteristic the most common forms are Baal hamman the chief deity of Punic north Africa perhaps the glowing Baal the god of fertilizing warmth and Baal shamem Baal of the heavens (cf Dan xii 11 xi 31 etc) The latter deity was widely venerated throughout the north Semitic world his name which does not appear in the Phoenician inscriptions before the 3rd century B C goes back at least to 800 B C (Aramaic inscription of Zakir from Hamath) The worship of the female along with the male principle was a strongly marked feature of Phoenician religion

To judge from earliest evidence on the subject the Baalath of Gebal or Byblus referred to again and again in the Amarna letters (*Beht sa Gubla* Nos 68-125) must have been the most popular of the Phoenician deities as her sanctuary was the oldest and most renowned The *mistress of Gebal* was no doubt Astarte (Astarte in Greek Ashtoreth in the Old Testament pronounced with the vowels of *bosheth* shame) a name which is obviously connected with the Babylonian Ishtar and as used in Phoenician is practically the equivalent of goddess She represented the principle of fertility and generation the common epithets *Kóρπις* and *Κυθέρεια* (of Kuthera in Cyprus) Cypria and Paphia show that she was identified with Aphrodite and Venus Though not primarily a moon goddess, she sometimes appears in this character (Lucian, *Dea syr*, § 4, Herodian v 6 10), and Herodotus describes her temple at Ashkelon as that of the Heavenly

Apollonius. We note a connection with Paul and the name of Baal, perhaps his transmitter. Another local deity, perhaps Carthage is Tanith (pronounced under an 'h') known to her character. He is closely connected with Baal, the Carthaginian deity, and called the face of Baal, as his type is revealed through some question his rendering of a word, and the face of Baal to be the name of a piece like P. (the of E). Two or three other deities have been mentioned here. Elmh is the god of violence and health, to Hippocrates, but also at Carthage and in the colonies, then mentioned by the Greeks with Aesculapius. Melqarth the patron deity of Tyre identified with Heracles. Reshef or Rehus the name of a lightning god especially popular in Cyprus and derived originally from Syria whom the Greeks called Apollo. A tendency to form distinct deities by combining the attributes of two produced such curious fusions as Milk ashtart, Milk baal, Milk osir, Eshmun, Melqarth, Melqarth Reshef, etc. As in the case of art and industry, in religion the Phoenicians readily assimilated foreign ideas. The influence of Egypt was especially strong (NSI pp 6, 69, 148, 154). The Phoenician settlers at the Peiræus worshipped the Assyrian Nergal and their proper names are compounded with his name of Babylonian and Arabian deities (NSI p 101). Closer intimacy with the Greek world naturally brought about modifications in the character of the native gods which became apparent when Baal of Sidon or Baalshamem was identified with Zeus, Tanith with Demeter or Artemis, Anath with Athena, etc. the notion of a supreme Baal which finds expression in the Greek θεὸς βααλ or βααλθεὸς (the goddess of Byblus) was no doubt encouraged by foreign influences. On the other hand the Phoenicians produced a considerable effect upon Greek and Roman religion especially from the religious centres in Cyprus and Sicily. A great number of divinities are known only as elements in proper names, e.g. *Sakun yathon* (Sanchuniathon). *Abd sasom*, *Sid yathon* and fresh ones are continually being discovered. It was the custom among the Phoenicians as among other Semitic nations to use the names of the gods in forming proper names and thus to express devotion or invoke favour, thus Hannibal, Abd melqarth, Hanni ashtart, Eshmun azar. The proper names further illustrate the way in which the relation of man to God was regarded: the commonest forms are *servant* (abd e.g. Abd ashtart), *member* or *limb* (bod e.g. Bod melqarth), *client* or *guest* (ger e.g. Ger eshmun), the religious idea of the *guest* of a deity had its origin in the social custom of extending hospitality to a stranger and in the old Semitic right of sanctuary.

**Sacred Objects and Worship**—Probably like other Canaanites the Phoenicians offered worship on every high hill and under every green tree, but to judge from the allusions to sanctuaries in the inscriptions and elsewhere the Baal or Ashtart of a place was usually worshipped at a temple which consisted of a court or enclosure and a roofed shrine with a portico or pillared hall at the entrance. In the court sometimes stood a conical stone, probably the symbol of Astarte as on the Roman coins of Byblus (see Ohnefalsch Richter *Cyprus* pl lvi the temenos at Idalion). Stone or bronze images of the gods were set up in the sanctuaries (NSI Nos 13 seq 23-27, 30 etc) and besides these the *baetyla* (meteoric stones) which were regarded as symbols of the gods. Pillars again had a prominent place in the court or before the shrine (*nasab* *ibid* pp 102 seq and W R Smith *Rel of Sem* pp 203 ff 456 ff) but it is not known whether the sacred pole (*asherah*) an invariable feature of a Canaanite sanctuary was usual in a Phoenician temple. The inscriptions mention altars of stone and bronze and from the sacrificial tariffs which have survived we learn that the chief types of sacrifice among the Phoenicians were analogous to those which we find in the Old Testament (NSI p 117). The ghastly practice of sacrificing human victims was resorted to in times of great distress (e.g. at Carthage Diod xx 14) or to avert national disaster (Porphyry *de Abstin*, ii 56) it was regarded as a patriotic act when Hamilcar threw himself upon the pyre after the disastrous battle of Himera (Herod vii 167). The god

who demanded the victim and especially the burning of children seems to have been Milk, the Molech or Moloch of the Old Testament. In connection may be mentioned the custom of burning the chief deity in the city or in the person of a human representative of a Tyrian deity in the Tyrian colonies such as Carthage and Cádiz. He was burned down to a late time (see Frazer *Idol* 115 ff) and the other horrible sacrifices.

Phoenician religion on women sacrificed her virginity to the bride of Astarte in the belief that they thus procured the good will of her favour (Pel of Sem 396). Intensive warfare was the natural accompaniment of the worship of the reproductive powers of nature. These temple prostitutes are called *qed shim qeas* both sacred men and women in the Old Testament (Deut xxiii 18, I Kings xiv 4 etc). Other persons attached to a temple were priests, augurs, sacrificers, barber officials in charge of the curtain, mason, etc. (NSI No 10) we hear also of religious guilds and corporations, perhaps administrative councils associated with the sanctuaries (*ibid* pp 94, 111, 130, 144 seq).

**Mythology and Religious Ideas**—No doubt the Phoenicians had their legends and myths to account for the origin of man and the universe to some extent these would have resembled the ideas embodied in the book of Genesis. Two cosmogonies have come down to us which though they differ in details are fundamentally in agreement. The one of Sidonian origin is preserved by Damascius (*de prim principis* 15) and received at his hands a Neoplatonic interpretation; the other and more elaborate work was composed by Philo of Byblus (temp Hadrian) he professed that he had used as his authority the writings of Sanchuniathon (*qv*) an ancient Phoenician sage who again derived his information from the mysterious inscribed stones (*αμμουνηεις* = *ammonais* = images or pillars of Baal hamman) in the Phoenician temples. Philo's cosmogony has been preserved at least in fragments by Eusebius in *Præp e ang* vol 1 (*Fr hist gr* iii 563 seq). It cannot however be taken seriously as an account of genuine Phoenician beliefs. At the same time Philo did not invent all the nonsense which he has handed down: he drew upon various sources Greek and Egyptian, some of them ultimately of Babylonian origin and incidentally he mentions matters of interest which when tested by other evidence are fairly well supported. He shows at any rate that some sort of a theology existed in his day, particularly interesting is his description of the symbolic figure of Cronus with eyes before and behind and six wings open and folded (*Fr hist gr* iii 569) a figure which is represented on the coins of Gebal Byblus (2nd century B.C.) as the mythical founder of the city. It is evident that the gods were regarded as being intimately concerned with the lives and fortunes of their worshippers. The vast number of small votive tablets found at Carthage prove this: they were all inscribed by grateful devotees to the lady Tanith, Face of Baal and the lord Baal hamman because he heard their voice. The care which the Phoenicians bestowed upon the burial of the dead has been alluded to above: pillars (*masseboth*) were set up to commemorate the dead among the living (e.g. NSI Nos 18, 19, 21, 32) if there were no children to fulfil the pious duty a monument would be set up by a man during his lifetime (*ibid* No 16 cf 2 Sam xviii 18). Any violation of the tomb was regarded with the greatest horror (*ibid* Nos 4, 5). The grave was called a resting place (*ibid* Nos 4, 5, 16, 17) and the departed lay at rest in the underworld with the *Refaim*, the weak ones (the same word and idea in the Old Testament Isa xiv 9, xxvi 14, 19, Job xxvi 5, Ps lxxxviii 10 etc). The curious notion prevailed as it did also among the Greeks and Romans that it was possible to communicate with the gods of the underworld by dropping into a grave a small roll of lead (*tabella devotionis* NSI No 50) inscribed with the message generally a curse which it was desired to convey to them.

**PHOENIX**, the capital and largest city of Arizona U S A and the county seat of Maricopa county on the Salt River at an altitude of 1100 ft midway between El Paso and Los Angeles

WEATHER GRAPH OF PHOENIX ARIZONA THE MERCURY INDICATES THE NORMAL ANNUAL MEAN TEMPERATURE AND THE CURVES SHOW THE MONTHLY MAXIMUM AVERAGE AND MINIMUM MEAN TEMPERATURES THE BLOCK SHOWS THE POSSIBLE SUNSHINE PERCENTAGE AND THE SHADED SPOTS INDICATE THE NORMAL MONTHLY PRECIPITATION

It is on Federal highways 80 and 89 has a municipal airport and is served by the Santa Fe and the Southern Pacific railways. The population was 90,511 in 1900 (81% native white) and was in 1930 48,118 by the Federal census. The climate of the Salt River valley is mild, dry and clear and Phoenix is an important health and pleasure resort. The average monthly mean temperature ranges from 51.2 F in December to 89.8 in July; the average annual precipitation is 7.87 inches; the amount of possible sunshine averages 84%. It is estimated that tourists spend \$3,000,000 in the city in a year. The city occupies 5.5 sq mi in a vast saucer-like valley encircled by mountains which is irrigated from the Roosevelt dam 70 mi NE and other projects. Cotton (largely a long staple variety), alfalfa, lettuce, cantaloupes, grapes, citrus fruits, olives, apricots, and other fruits and vegetables are leading crops. Date palms, pepper and eucalyptus trees and the magnificent saguaro cactus are features of the landscape. The state capitol of native tufa is set in a 10-acre park where all the trees and shrubs indigenous to the region are represented. The Papago Saguaro National Monument (1,940 acres) lies 3 mi E, 6 mi S is the city's mountain park of 14,000 acres. At Tempe 8 mi E is a State Teachers college and the State experimental farm is near Mesa 15 mi SE. Phoenix has an assessed valuation of \$57,658,821 (1928), bank deposits on June 30, 1928 aggregated \$36,677,801 and post office receipts for 1927 were \$428,637. Since 1914 it has had a commission manager form of government. Phoenix was founded in 1871, incorporated in 1881 and became the capital of Arizona in 1889. In 1890 the population was 3,151; in 1900 5,544; in 1910, 11,134. Between 1910 and 1920 it increased 161%.

**PHOENIX**, a fabulous bird sacred to the sun (Gr *Φοινίξ* apparently 'bright coloured'; *φοινίξ* also means a palm tree). From statements in a large number of classical and post-classical authors, ranging from the 5th century B.C. (Herodotus perhaps Hecataeus) to the Middle Ages (Isaac Tzetzes), the following account is obtained. The phoenix was a large bird of very gorgeous plumage, having according to one or two authorities a sweet voice. It was always male, the only one of its kind and lived a long time (various authors give periods ranging from 500 years, the commonest account, up to 1,2954, Tacitus *Annales* vi 28-4 gives 1,461 years, which is an Egyptian Sothis period). At the expiration of that time it made itself a nest of twigs of

spice trees on which it died by setting the nest on fire and burning itself alive. From its body or its ashes or the nest which it had furnished came forth another phoenix, either perfect or at first in the shape of a white grub. This young bird as soon as it was strong enough took up the body of its father covered in spices or the ashes of the nest and all and flew to Heliopolis in Egypt where it deposited them on the altar of the Sun. There are numerous variants in detail; sometimes the phoenix goes to Egypt to die having produced its offspring before dying.

It was not doubted by the majority that the phoenix really was seen now and then in Egypt. Tacitus *loc cit* and Pliny *nat hist* x mention recorded appearances genuine and otherwise. Attention is therefore drawn by A. Wiedemann to the facts that a bird of the stork kind, the *bennu* or *bannu*, was sacred at Heliopolis and connected with the local sun worship; moreover that its name also means a palm tree. This certainly gives a plausible origin for some parts of the Greek story and accounts for Herodotus's statement (ii 73-1) that he saw a picture of it in Egypt, for the *bennu* is to be found on surviving monuments. But it fails to account for the persistent statement that the phoenix is not a native of Egypt but lives in Arabia, Assyria, Ethiopia or India, nor does the real or pictured *bennu* at all resemble the phoenix as described. Hence it is likely that the ultimate origin of the story, however it may have reached Greece, is to be sought in the mythology of one or another of these countries.

Many commentators still understand the word *חול* *chol* in Job xxix 18 (in King James's Version *sand*) to apply to the phoenix. This interpretation is perhaps as old as the (original) Septuagint and is current with the later Jews. Among the Arabs the story of the phoenix was confused with that of the salamander and the samand or samandal (Damiri ii 36 *et seq*) is represented sometimes as a quadruped, sometimes as a bird. It was firmly believed in for the incombustible cloths woven of flexible asbestos were popularly thought to be made of its hair or plumage and were in fact called by the same name (cf. Yaqut i 329 and Dozy *sv*). The *anka* (Pers. *simurgh*), a stupendous bird like the roc (*ruk*) of Marco Polo and the *Arabian Nights*, also borrows some features of the phoenix. According to Kazwini (i 420) it lives 1,000 years and when a young bird is hatched the parent of opposite sex burns itself alive.

Ancient and modern authorities are collected and analysed by Türk in Roscher's *Lexikon* iii col. 3450 *et seq*.

#### PHOENIX ISLANDS see PACIFIC ISLANDS

**PHOENIXVILLE**, a borough of Chester county, Pennsylvania, U.S.A., on the Schuylkill river at the mouth of French creek, 28 mi NW of Philadelphia, served by the Pennsylvania and the Reading railways. Pop. (1920) 10,484 (80% native white); in 1930 it was 12,029. It has extensive iron and steel works making steel bridges, architectural steel, boilers and many other products, also underwear, silk and silk hosiery mills. The aggregate manufactured output in 1927 was valued at \$12,128,419. Phoenixville was settled in 1732 and incorporated in 1849.

**PHOLIDOTA**, an order of mammals comprising only the scaly anteaters (Mamidae) of Asia and Africa. The order was formerly united with the Xenarthra and Tubulidentata (*qv*) as the order Edentata (*qv*). (See also PANGOLIN.)

**PHONETICS** is the science of the pronunciation of languages. It is concerned with the mechanism by which speech sounds are formed, the manner of combining sounds so as to make syllables, words and sentences, the treatment of speech sounds in different languages as regards their attributes (length, stress and voice pitch), the *timbre* (acoustic quality) of speech sounds and groups of speech sounds, the methods of representing speech sounds by means of writing (including transcripts for language learners, spelling reform and the writing of languages hitherto unwritten).

Phonetics has two main practical objects: (1) to help learners of foreign languages to hear accurately and to pronounce accurately and (2) to enable those who are concerned with the spelling or writing down of languages to devise the simplest and most practical system for each language.

**Phonetic Analysis**.—In order to effect either of these prac-

—The "received" form of a language is a kind of foreign language to those who speak dialects or speak with special "accents." The

methods of teaching received pronunciation are therefore similar to those followed in teaching a foreign language. Some of the sound of received pronunciation will be new to the pupil and must be taught by means of exercises which he phonetically trained teacher invents to suit his particular needs. His natural pronunciation may also differ from received pronunciation in other respects and particularly by the use of a different distribution of known sounds as when a Londoner makes the last syllable of *opposite* rhyme with *mign* or when a native of Lincolnshire gives to the *u* in *butcher* the same value as it has in *cut*. Here phonetic transcriptions are useful for showing the difference of sound.

**Phonemes**—When the sounds existing in a given language have been analysed it is always found that some of them may be regarded as variants of other which they replace in certain well defined conditions. A family consisting of one distinctive sound of the language together with the variants which represent it in particular sound combinations is called a phoneme. The nature of a phoneme is best shown by examples. The three *k*'s in *keep cool cot* are different sounds but for practical purposes they may be treated as a single entity: they are said to belong to the same phoneme. The precise *k* sound used in any particular case is determined by the nature of the neighbouring sounds and the different varieties are not used for the purpose of distinguishing English words. Similarly the three *t* sounds in *eight eighth train* belong to one phoneme because the variants in *eighth* (phonetically *eiθ*) *train* are dependent upon the neighbouring sounds *θ* *r*. The French sounds *l* and *l* (voiceless *l*) are members of the same phoneme. *l* is used in French only in final position when a consonant precedes as when the word *boucle* occurs at the end of a sentence: ordinary voiced *l* does not occur in this position and consequently a Frenchman naturally regards the two very dissimilar sounds *l* and *l* as a single entity.

It often happens that sounds which belong to one phoneme in one language constitute separate phonemes in another language: they are consequently used for the purpose of distinguishing words in the second language though not in the first. Thus *l* and *l* are separate phonemes in Welsh, Burmese and Zulu though they constitute only one phoneme in French (*l* is transcribed *l* when it is a separate phoneme). Again *h* and *ç* (the German *ich* sound) are separate phonemes in German but *ç* is a member of the *h* phoneme in Japanese (the sound used when *i* follows). The French sounds of *e* and *e* are separate phonemes in French and are used for distinguishing words in that language but similar sounds occur in Russian and in Zulu as members of one phoneme: their use being determined in Russian by the nature of the adjacent consonants and in Zulu by a principle of vowel harmony.

Phonemes are families of sounds occurring in a language as pronounced by a single individual. They must be distinguished from diaphones (see below) which contain sounds used by two or more different speakers of a language.

The simplest system of phonetic transcription of a language is that which provides one symbol for each phoneme of that language. Such a system is known as broad transcription. It is unambiguous to the native and to anyone who knows the rules governing the use of the subsidiary members of the phonemes. More detailed transcriptions providing symbols for subsidiary members of phonemes are called narrow transcriptions. They are useful in comparative work, dialectology, etc.

**Diaphones**—Speakers of the same language often do not all use exactly the same sounds. Thus the vowel element of the word *day* is pronounced in several different ways according to the locality and to the social position of the speaker (phonetically *de* *dei* *dei* *dee* *dæi* etc.). In such cases it is convenient to have a term to denote the family of sounds consisting of a sound of a language as pronounced by an average speaker together with other sounds which are used in place of it by other speakers. Thus the various vowel sounds used in the word *day* by different speakers of English are said to constitute one diaphone in the English language.

**Phonetic Symbols**—In nearly every language the number of phonemes is greater than the number of letters in the Roman

alphabet. It is therefore impossible to represent most languages unambiguously by means of the ordinary Roman letters only. So any phonetic system whether designed as a current orthography or as a transcription for the use of language learners must contain new letters to supplement those of the present Roman alphabet. It can be shown that on psychological typographical and pedagogical grounds specially designed letters are better than ordinary Roman letters with diacritical marks attached. In the designing of new letters several factors have to be taken into consideration the chief of which is that the printed forms of the letters should harmonize as well as possible with the ordinary Roman characters so that the general appearance of the printed page may be satisfactory. It must also be possible to write the new letter with ease. It is further desirable that the letters should have italic forms which do not differ from the Roman forms in any essential part of their outline. To ensure legibility it is necessary that each letter should be as different as possible from every other letter. For typographical reasons the letters should as far as possible be designed so as to avoid the necessity of kerned types. Kerns at the top or bottom of the type are entirely inadmissible. Kerns at the side are undesirable and must be resorted to as sparingly as possible but it does not seem possible in a comprehensive alphabet to avoid them altogether. Lastly it is a great advantage that the phonetic alphabet as a whole should be international: that is to say that each letter should always be used with the same or approximately the same value.

Of the phonetic alphabets hitherto invented only one that of the International Phonetic Association complies satisfactorily with the above mentioned requirements. The next best is the Swedish dialect alphabet (which in spite of its name is really international).

**Manner of Using a Phonetic Alphabet**—In constructing phonetic orthographies or in making phonetic transcripts for

FIG 1—DIAGRAM ILLUSTRATING ORGANS OF SPEECH  
FIG 2—TONGUE POSITIONS OF THE FRONT CARDINAL VOWELS  
FIG 3—TONGUE POSITIONS OF THE BACK CARDINAL VOWELS

language students attention must be given not only to the designs of any special letters that may be required but also to the manner of using the alphabet. This will depend (1) on the precise purpose for which the alphabet is required and (2) on the structure of the particular language or languages dealt with. Thus if the writer's purpose is to make a comparative study of related languages he may be obliged to mark distinctions which it would be unnecessary to mark in a transcript of one language for the use of those who wish to learn to speak it.

THE INTERNATIONAL PHONETIC ALPHABET

	Bilabial	Labiodental	Dental	Retrolabial	Palatal	Alveolar	Palatoalveolar	Velar	Uvular	Pharyngeal	Glottal
CONSONANTS	Plosive	p b		t d				k g	q ɢ		ʔ
	Nasal	m	ɱ	n	ɳ			ŋ	ɴ		
	Lateral plosive			ɖ ɗ							
	Lateral fricative			ɬ ɮ							
	Rhotic			r					ʀ		
	Flap			ɾ					ʁ		
	Fricative	ɸ β	f v	θ ð	s z	ʃ ʒ	ʂ ʐ	ç ʝ	x ɣ	ħ ʕ	h ɦ
VOWELS	Frontal	ɪ	ʏ	ʉ	ɛ	æ	ɐ				
	Central	ɨ	ɜ	ɞ	ɔ	ɔ̃	ɔ̄				
	Back	ʊ	ʊ	ʊ	ʊ	ʊ	ʊ				
	Glottal	ʔ	ʔ	ʔ	ʔ	ʔ	ʔ				

(See ordinary phonetic symbols in brackets)

OTHER SOUND — Palatalized consonants *ṭ ḍ* etc Velarized or pharyngealized consonants *k̠ g̠* etc Ejective consonants (plosives with simultaneous glottal stop) *pʰ tʰ* etc Implosive voiced consonants *ɓ ɗ* etc Fricative trill *ʀ ʁ* (labialized *θ ð* or *s z*) *ʃ̣ ʒ̣* (labialized *ʃ ʒ*) *ɬ̣ ɮ̣* (clicks Zulu *c q x*) *ɬ̤ ɮ̤* (a sound between *r* and *l*) *ɰ* (voiceless *w*) *ɸ* (a vowel between *ɪ* and *o*)

Affricates are normally represented by groups of two consonants (*ts tʃ dʒ* etc) but when necessary ligatures are used (*ʈ ʈʂ* etc) or the marks *͡* or *͜* (*ts̺* or *ts̺̺* etc) *ɟ ʝ* may occasionally be used in place of *tʃ dʒ* Aspirated plosives *ph th* etc

LENGTH STRESS PITCH — (full length) (half length) (stress placed at beginning of the stressed syllable) (secondary stress) (high level pitch) (low level) (high rising) (low rising) (high falling) (low falling) *ˆ* (rise fall) *ˊ* (fall rise) See *Ecriture Phonétique Internationale* p 9

MODIFIERS — *̃* nasality *̤* breath (*ɬ̤* = breathed *ɬ*) *̥* voice (*ʂ̥* = *ʂ*) slight aspiration following *p t* etc specially close vowel (*e̝* = a very close *e*) specially open vowel (*e̞* = a rather open *e*) labialization *n̠* = labialized *n* *̠* dental articulation (*t̠* = dental *t*) palatalization (*ʒ̟* = *ʒ*) tongue slightly raised *ɔ̟* lips more rounded *ɔ̠* lips more spread (*e̠* *ɲ*) syllabic consonant *̥* consonantal vowel *̥* variety of *ʃ* resembling *s* etc

**Classification of Speech sounds**—The above table of the International Phonetic symbols taken in conjunction with the chart of the organs of speech (fig 1) shows the chief principles of sound classification The meanings of most of the technical terms describing the various classes of sounds are self evident Attention may however be called to the following which require some explanation The back of the tongue is the part which lies normally opposite the soft palate (velum) the front is the part which lies normally opposite the hard palate the blade is the part which lies normally opposite the teeth ridge (upper gum alveolars) Palatal consonants are those formed by the front of the tongue against the hard palate such as the English sound of *y* or the German *ch* in *ich* Retroflex consonants are those made by the tip of the tongue against the hard palate such as the Hindi sounds of *ɖ ʂ*

**Classification of Vowels**—Vowels are classified (1) according to the position of the tongue and (2) according to the position of the lips In forming a vowel the opening between the lips and the distance of the tongue from the palate must be sufficient to ensure that there is no audible friction when voice is emitted The lips may be spread (as for the English *ee* sound) or they may have close rounding (as in the sound of *u* in *rule*) or open rounding (as in the vowel in *long*) The classification of vowels according to tongue positions and the terminology employed in describing vowels is shown in figs 2 3 and 4 The relative tongue positions of vowels may be indicated by dots placed on the vowel figure (fig 4)

**Cardinal Vowels**—In order to give an intelligible description of the vowels of any language it has been found necessary to establish a system of cardinal vowels These are the vowels

marked by the large black dots in fig 4 The eight primary cardinal vowels are represented by the letters *i e ε a ɑ ɔ o u* these are numbered 1 to 8 respectively Eight secondary cardinal vowels are represented by *y ø œ ɐ ɒ ʌ ɘ ɯ* (numbered 9 to 16 respectively) (No letter has been adopted for secondary cardinal vowel No 1 as it has not been found to exist as a separate phoneme in any language) They have the same tongue positions as the primary cardinal vowels but different lip positions Nos 9 to 13 have lip rounding and Nos 14 15 16 have lip spreading The tongue positions of any vowel may be represented by a dot at the appropriate place on the cardinal vowel chart This marking together with a description of the lip position shows the language learner exactly how the vowel is formed and gives him a good idea of what it sounds like Thus a foreign learner who has never heard English can learn to make the vowel of *cat* when he knows that it is half way between cardinal vowels 3 and 4 (*ε* and *a*) An Englishman learning Italian without a teacher can get a good idea of what the Italian vowels sound like from a diagram (fig 5) which shows the relationship of the Italian vowels to the cardinal vowels

In transcribing particular languages the cardinal vowel letters are used to represent sounds in the vicinity of the cardinal vowel sounds The letters in fact serve to represent vowels lying within certain areas on the vowel figure as shown in fig 2 In the comparatively unusual cases when two vowel sounds within the same cardinal area are used for the purpose of distinguishing words additional vowel letters have to be introduced Such are *ɪ* (used for the English vowel in *sit*) *ʊ* (used for the English vowel in *put*) *ʏ* (used for the German vowel in *Glück*) *æ* is commonly used for the vowel in *cat*, which lies in the left upper

The term phonolite is often used to describe a group of rocks which are rich in alkalis and contain much nepheline and sanidine. The term is derived from the Greek words *phōnē* (sound) and *lithos* (stone). These rocks are often found in volcanic regions and are characterized by their fine-grained texture and the presence of large, flat, tabular crystals of nepheline and sanidine.

In the field of phonolite reproduction, there has been no real progress within the last few years. The trend has been towards the use of electrical methods rather than mechanical. The wide range of frequencies and loudness which can be obtained by the use of electrical methods and the impact with which the loudness can be controlled probably mainly responsible for this trend. While for small scale instruments it is still possible to obtain a good reproduction with the mechanical machine, the improvements in the electrical methods of reproduction have caused him to have to take precedence in the higher priced field.

**PHONOLITE**, in petrology a group of alkaline lavas containing much nepheline and sanidine feldspar (Gr. *phōnē* sound and

*lithos* stone). The term is often used to describe a group of rocks which are rich in alkalis and contain much nepheline and sanidine. The term is derived from the Greek words *phōnē* (sound) and *lithos* (stone). These rocks are often found in volcanic regions and are characterized by their fine-grained texture and the presence of large, flat, tabular crystals of nepheline and sanidine.

These rocks are often found in volcanic regions and are characterized by their fine-grained texture and the presence of large, flat, tabular crystals of nepheline and sanidine.

Leucite occurs in place of nepheline in a small group of phonolites (the leucite phonolites) known principally from Rocca Monfina and other places near Naples. When sanidine, nepheline and leucite all occur together in a volcanic rock it is classed among the leucitophyres (see PETROLOGY).

**PHORMION**, Athenian admiral in the 5th century B.C. was the son of Asopius of the deme Paeania. He first appears in 440 B.C. when he was sent with reinforcements to the Athenian troops

	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	FeO	Fe <sub>2</sub> O <sub>3</sub>	MgO	CaO	Na <sub>2</sub> O	K <sub>2</sub> O	H <sub>2</sub> O

III Leucite phonolite Rocca Monfina Italy	58.40	10.36		4.99	0.53	60	3.14	10.47	0.4

*lithos*, stone). The term clinkstone was formerly given by geologists to many fine grained compact lavas which split into thin tough plates and gave out a ringing sound when struck with the hammer. Some of these were phonolites in the modern sense but as the name clinkstone was used for a large variety of rocks many of which have no close affinities with one another it has been discarded and phonolite substituted. The group includes rocks which are rich in alkalis with only a moderate percentage of silica hence they contain no free quartz but much alkali feldspar (sanidine and anorthoclase) and nepheline. Large plates of sanidine are often visible in the rocks the nepheline is usually not obvious to the unaided eye. Most phonolites show fluxion structure both in the orientation of their phenocrysts and in the smaller crystals which make up the ground mass and this determines to a large extent the platy jointing. Although vitreous and pumiceous forms are known they are rare and in the great majority of cases these rocks are finely crystalline with a dull or shimmering lustre in the ground mass.

**Dominant Minerals.**—These are sanidine, nepheline, pyroxene, amphibole, various feldspaths and iron oxides. The sanidine is usually in two generations the first consisting of large crystals of flattened and tabular shape while the second is represented by small rectangular prisms arranged in parallel streams in the ground mass these feldspars are nearly always simply twinned on the Carlsbad plan. They contain often as much soda as potash. The nepheline takes the form of hexagonal prisms with flat ends and may be completely replaced by fibrous zeolites so that it can only be recognized by the outlines of its pseudomorphs. In some phonolites it is exceedingly abundant in the ground mass and these rocks form transitions to the nephelinites (nephelinitoid phonolites), in others it is scarce and the rocks resemble trachytes containing a little nepheline (trachytoid phonolites). The feldspathoid minerals sodalite, hauyne and nosean which crystallize in isometric dodecahedra, are very frequent components of the phonolites their crystals are often corroded

before Samos. In 431 he took out reinforcements to the force blockading Potidaea took over the command from Callicles and completed the circumvallation of the city. He seems to have stayed in the north east as in 431 he was co-operating with Perdiccas against the Chalcidians. In 430 he was sent with 30 ships to help the Acarnanians against the Ambraciots. That winter there followed the operations on which his fame is based. He was given 20 ships and stationed at Naupactus to effect a blockade of Corinth from that side. In the summer of 429 a superior Peloponnesian fleet arrived and was decisively beaten by Phormion. In a second engagement he was forced to retreat but turned and again routed his pursuers. He was probably dead by 428.

**PHORMIUM** or **NEW ZEALAND FLAX** (also called New Zealand hemp) a fibre obtained from the leaves of *Phormium tenax* (family Liliaceae) a native of New Zealand the Chatham islands and Norfolk island. This plant was discovered by Sir Joseph Banks and Dr. Solander who accompanied Captain Cook on his first voyage of discovery. It grows luxuriantly in the south of Ireland where it was introduced in 1798 and also flourishes on the west coast of Scotland and is generally cultivated as an ornamental garden plant in the warmer parts of Europe and North America. It has been introduced for economic purposes into the Azores and California. The name *Phormium* is from Gr. *phormiōs* a basket in allusion to one of the uses made of its leaves by the New Zealanders. It has a fleshy rootstock creeping beneath the surface of the soil and sending up luxuriant tufts of narrow sword-shaped leaves from 4 to 8 ft. long and from 2 to 4 in. in diameter. The leaves are vertical and arranged in two rows as in the garden flag they are very thick, stiff and leathery dark green above paler below, with the margin and nerve reddish orange. From the centre of the tuft ultimately arises a tall flower bearing stem 5 to 15 ft. high bearing on its numerous branches a very large number of lund red or yellow somewhat tubular

flowers receding to one or another side from the long axis. After flowering the plant dies down but increases by new lateral growths from the root stock. The plant will grow in almost any soil but best on high rich soil by the side of rivers and brooks where sheltered from the wind.

Phormium is a cream coloured fibre with a fine silky gloss capable of being spun and woven into many of the heavier textures for which flax is used either alone or in combination with flax. It is however principally a cordage fibre and in tensile strength it is second only to manila hemp but it does not bear so well the alternations of wet and dry to which ship ropes are subject.

**PHORONIS** *Phoronis* is one of those limbless creatures popularly termed worms. It is however so peculiar in its structure that it is given a class to itself Phoronidea. There are a good many species found all over the world but they are so alike that they are placed in a single genus *Phoronis* although they vary from  $\frac{1}{2}$  in to 6 in in length. *Phoronis* is marine and lives in a leathery tube from which the fore part of the body can be protruded. The front part carries a peculiar platform or lophophore crowned with beautiful upright tentacles covered with cilia which are in perpetual motion. In *P. hippocrepea* the lophophore is shaped like a horse shoe and the tentacles are arranged along its edge those on the concavity of the shoe being somewhat the shorter. All species have lophophores more or less of this shape but the tips of the shoe are in some much more prolonged than in others and even inrolled. The cilia produce a current which sweeps small organisms into the mouth situated between the outer and inner row of tentacles. It is elongated and slit like and provided with a covering lip the epistome which projects from the concave side of the lophophore. Below the lophophore on the side of the concavity of the horseshoe the anus projects as a little papilla. At the sides of the anus two smaller papillae carry the openings of a pair of ciliated tubes which connect the body cavity with the exterior. These tubes (*coelomoducts*) serve to get rid of the excreta in the body cavity fluid and to let out the germ cells when these are ripe.

Since the mouth and anus are close together and the animal has a long worm like body it is obvious that the alimentary tube will be U shaped. The long gullet leads into a globular stomach lying at the lower end of the body from which the long slender ascending intestine leads to the anus. The first part of the intestine where it leaves the stomach is swollen lined by ciliated epithelium and devoid of glands. The alimentary tube is enswathed by a true secondary body cavity or coelom which is lined by an epithelium the outer layer of which is pressed against the body wall whilst the inner layer lies against the gut cells. This cavity is divided into two by a horizontal platform just behind the mouth. The front portion communicates with the cavities of the tentacles and of the epistome. This is the lophophoral coelom the hinder portion in which the gullet and intestine lie and into which the coelomoducts open is the trunk coelom and is traversed by a median septum or mesentery which ties the outer side of the oesophagus to the body wall in addition the oesophagus is anchored by two lateral mesenteries. These mesenteries however cease before the stomach is reached. The genital cells appear as thickenings of the inner wall of the coelom and both male and female are produced by the same individual in separate swellings projecting from the wall of the stomach. The trunk coelom is thus divided into three chambers, a right and left lateral on the convex side of the lophophore and a large rectal chamber on the concave side. In this latter lies the intestine which is tied to the body wall by its own independent mesentery and is also fused by its side to one of the lateral mesenteries.

Each coelomoduct opens into the body cavity by two funnel shaped openings lined by cilia a short one communicating with the lateral chamber and a long slit like one opening into the rectal chamber.

The nervous system is simple consisting merely of an interlacing mass of extremely fine fibrils and small nerve-cells which thickens to form a horizontal band passing around the lophophore and giving off a special branch to each tentacle. There is also a thickening in the skin of the epistome.

The life of *Phoronis* consists merely in expanding the front of the body erecting the tentacles and working the cilia vigorously the mouth being opened wide to catch whatever fortune brings. On the approach or danger the whole body is withdrawn within the tube. This is effected by bands of longitudinal muscles in the body wall—the expansion being brought about by circular muscles which by compressing the body force fluid into the lophophore and engorge it.

The interest of *Phoronis* lies in its strong resemblance to certain *Polysa* (q.v.) Lankester went so far as to call *Phoronis* the only solitary polyzoon. But *Phoronis* possesses distinct altogether from the body cavity a well developed blood system containing a colourless serum in which float red blood corpuscles. No such organ is found in any polyzoon. This blood system consists of an artery running on the anal side of the gullet to the level of the lophophore where it gives off right and left a vessel to each arm of the lophophore. From these a single vessel goes to each tentacle. This vessel at the base of the tentacle sends a fork to an outer or recipient vessel which runs along the convex side of the lophophore on each side. The right and left recipient vessels pass downwards pierce the lophophoral platform and unite on the convex side of the oesophagus to form a single vein which below the stomach opens into the artery.

The reproduction raises other questions. The eggs after being shed stick to the tentacles and are there fertilized by sperms from another individual. They complete the first stages of their development within the egg membrane from which they hatch out as peculiar free swimming larvae known as *Actinotrocha*. This larva is provided with a ciliated forehead in which a large ganglion is embedded. There is an oblique wreath of ciliated tentacles behind the mouth by which it swims. There is a belt of cilia round the hind end of the body in front of the anus. This larva after feeding for a time and growing greatly in size develops an intucking of skin on its under surface to which a fold of the intestine becomes attached. Suddenly (inside a quarter of an hour) this intucked area is everted forming a finger shaped process containing a loop of the intestine which gives rise to the body of the worm. The ciliated forehead is cast off as are also the ciliated tentacles but new tentacles which give rise to the lophophore of the adult are regenerated from their stumps. This larva with its extraordinary life history has given rise to much speculation. We owe the clearing up of its real affinities to E. S. Goodrich and Shearer who have shown that *Actinotrocha* is merely a modified trochophore such as occurs in the life history of the Gephyrea amongst the Annelida (q.v.). The typical trochophore has a broad preoral belt of cilia the *prototroch* and a slender postoral one the *metatroch* whilst a belt of cilia the *telotroch* encircles just in front of the anus. (E. W. MACB.)

**PHORORHACOS**, a gigantic extinct Patagonian bird allied to the Cranes and in some respects recalling the South American *Cariama* bird. About six species of the type genus have been discovered the most complete being *P. inflatus* with

OF THE SKULL OF PHORORHACOS LONGISSIMUS AN EXTINCT BIRD OF PREY

skull mandible pelvis limbs and some of the vertebrae. The skull of *P. longissimus* is about 2ft long and 10in high that of *P. inflatus* is 13in long and this creature is supposed to have stood only 3ft high at the middle of the back. The under jaw is slightly curved upwards. The strongly hooked upper beak is high and laterally compressed. The vomer is inconspicuous. The quadrate has a double knob for articulation with the skull and basipterygoid processes are absent. What little is known of the shoulder girdle points to a flightless bird and so do the short wing bones although these are stout. The pelvis has an ischiadic foramen. The hind limbs are distinctly slender the tibia of *P. inflatus* being between 15 and 16in in length.

**PHOSGENE** or **CARBONYL CHLORIDE**, an extremely poisonous, heavy gas came into prominence during the

[illegible]

**PHOSGENITE**, a rare mineral consisting of lead chlorocarbonate ( $\text{PbCl}_2\text{CO}$ ). The tetrahedral crystals are prismatic or tabular in habit and are bounded by smooth bright faces; they are usually colourless and transparent and have a brilliant adamantine lustre. Sometimes the crystals have a curious helical twist about the tetrad or principal axis. The hardness is 5 and the specific gravity 6.5. The mineral is rather sectile and consequently was early known as 'corneous lead'. The fanciful name phosgenite is from phosgene the old name of carbon oxychloride because the mineral contains the elements carbon, oxygen and chlorine. At Cromford in Derbyshire it was long ago found in an old lead mine being associated with anglesite and matlockite ( $\text{Pb}_2\text{OCl}_2$ ) in cavities in decomposed galena; hence its synonym cromfordite.

**PHOSPHATES**, salts of phosphoric acid. Phosphoric oxide  $\text{P}_2\text{O}_5$  or  $\text{P}_4\text{O}_{10}$  (Tilden and Barnett *op. cit.*) combines with water in three proportions to form  $\text{H}_3\text{PO}_3$  or  $\text{HPO}_3$  metaphosphoric acid,  $\text{H}_4\text{PO}_4$  or  $\text{H}_3\text{PO}_4$  pyrophosphoric acid and  $3\text{H}_3\text{PO}_3$  or  $3\text{HPO}_3$  orthophosphoric or ordinary phosphoric acid. These acids each give origin to several series of salts, those of ordinary phosphoric acid being the most important.

Orthophosphoric acid  $H_3PO_4$  a tribasic acid is obtained by boiling a solution of the pentoxide in water by oxidizing red phosphorus with nitric acid or white phosphorus under the surface of water by bromine or iodine and also by decomposing a mineral phosphate with sulphuric acid. It usually forms a thin syrup which on concentration in a vacuum over sulphuric acid deposits hard transparent rhombic prisms which melt at  $41^\circ C$ . After long heating the syrup is partially converted into pyrophosphoric and metaphosphoric acids but on addition of water and boiling the ortho acid is reformed. It gives origin to three classes of salts  $M'H_2PO_4$  or  $M'(HPO_4)_2$ ,  $M_2HPO_4$  or  $M'HPO_4$  and  $M_3PO_4$ ,  $M_3(PO_4)_2$  or  $M_2PO_4$  wherein  $M$ ,  $M'$ ,  $M''$  denote a univalent and trivalent metal. These correspond to  $H_3PO_4$  in which one, two or three atoms of hydrogen respectively have been replaced by a metal. The three principal groups differ remarkably in their behaviour towards indicators. Those of the first type are strongly acid, the second are neutral or faintly alkaline whilst the third are strongly alkaline and are decomposed by carbon dioxide  $Na_2PO_4 + CO_2 + H_2O = NaHCO_3 + Na_2HPO_4$ . The salts of the types  $NaH_2PO_4$  and  $CaH_4P_2O_8$  may be obtained in crystal form but those of the heavy metals are only stable when in solution. All soluble orthophosphates give with silver nitrate a characteristic yellow precipitate of silver phosphate  $Ag_3PO_4$  soluble in ammonia and in nitric acid. Since the reaction with the acid salts is attended by liberation of nitric acid  $NaH_2PO_4 + 3AgNO_3 = Ag_3PO_4 + NaNO_3 + HNO_3$ ,  $Na_2HPO_4 + 3AgNO_3 = Ag_3PO_4 + 2NaNO_3 + HNO_3$  it is necessary to neutralize the nitric acid if the complete precipitation of the phosphoric acid be desired. The three series also differ when heated: the trimetallous salts containing fixed bases are unaltered whilst the mono- and dimetallous salts yield meta- and pyrophosphates respectively. Other common precipitants of phosphoric acid or its salts in solution are ammonium molybdate in nitric acid which gives on heating a canary yellow precipitate of ammonium phosphomolybdate  $12[MoO_3] \cdot (NH_4)_3PO_4$  insoluble in acids but readily soluble in ammonia, magnesium chloride, ammonium chloride and ammonia which give on standing in a warm place a white crystalline

recipitate magnesium ammonium phosphate  $Mg(NH_4)PO_4 \cdot 6H_2O$  which is soluble in acid but highly insoluble in ammonia solution and on heating or redness it is magnesium pyrophosphate  $Mg_2P_2O_7$ .

O the organophosphorus triphenyl phosphite  $(C_6H_5)_3PO_3$  is important in the synthesis of doped and substituted for phosphorus in the polymer C and has to C

**Pyrophosphoric acid**  $\text{H}_4\text{P}_2\text{O}_7$  is a strong acid which may be regarded as a dimer of orthophosphoric acid. It is formed by the condensation of two molecules of ordinary phosphoric acid. It can be obtained by heating metaphosphoric acid. When boiled with water it forms the ortho acid and when heated to redness the meta acid. After neutralization it gives a white precipitate with silver nitrate. Being a tetrabasic acid it can form four classes of salts for example the four sodium salts  $\text{Na}_4\text{P}_2\text{O}_7$ ,  $\text{Na}_3\text{HPO}_7$ ,  $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$ ,  $\text{NaH}_3\text{P}_2\text{O}_7$  are known. The most important is the normal salt  $\text{Na}_4\text{P}_2\text{O}_7$  which is readily obtained by heating disodium orthophosphate  $\text{Na}_2\text{HPO}_4$ . It forms monoclinic prisms (with  $10\text{H}_2\text{O}$ ) which are permanent in air. All soluble pyrophosphates when boiled with water are converted into orthophosphates.

**Metaphosphoric acid**  $\text{HPO}_3$  or more correctly  $\text{H}_2\text{P}_2\text{O}_6$  as determined by vapour density (Tilden and Barnett) is a monobasic acid which may be regarded as derived from orthophosphoric acid by the abstraction of one molecule of water thus  $\text{H}_2\text{PO}_4 - \text{H}_2\text{O} = \text{HPO}_3$ , its constitution is therefore  $(\text{HO})\text{PO}$ . The acid is formed by dissolving phosphorus pentoxide in cold water or by strongly heating orthophosphoric acid. It forms a colourless vitreous mass hence its name glacial phosphoric acid. It is readily soluble in water the solution being gradually transformed into the ortho acid a reaction which proceeds much more rapidly on boiling. Although the acid is monobasic salts of polymeric forms exist of the types  $(\text{MPO}_3)_n$  where  $n$  may be 1, 3, 4 or 6. They may be obtained by heating a monometallic orthophosphate of a fixed base or a dimetallic orthophosphate of one fixed and one volatile base e.g. microcosmic salt  $\text{MH}_2\text{PO}_4 = \text{MPO}_3 + \text{H}_2\text{O}$   $(\text{NH}_4)_2\text{NaHPO}_4 = \text{NaPO}_3 + \text{NH}_3 + \text{H}_2\text{O}$ . The salts are usually non-crystalline and fusible. Their solutions on boiling yield orthophosphates whilst those of heavy metals give a trimetallic orthophosphate and orthophosphoric acid  $3\text{AgPO}_3 + 3\text{H}_2\text{O} = \text{Ag}_3\text{PO}_4 + \text{H}_3\text{PO}_4$ . Metaphosphoric acid can be distinguished from the other two acids by its power of coagulating albumen and by not being precipitated by magnesium and ammonium chlorides in the presence of ammonia. For perphosphoric acids see PHOSPHORUS

**PHOSPHORESCENCE** Physicists apply the word phosphorescence to the emission of light at low temperatures by certain substances (chiefly sulphides) after previous exposure to light or radiation of other kinds. However common usage has made it applicable to the glow of phosphorus or of the sea or of dead fish or meat or of wood the fox fire of forests. Phosphorescence of the sea or of flesh wood etc is due to living organisms of various kinds and should more properly be called bioluminescence. Such light is the result of a slow oxidation of material manufactured by the organism.

At least 40 different orders of animals contain luminous species and also two groups of plants the bacteria responsible for the luminescence of flesh and the fungi responsible for the luminescence of wood. Either the fine strands of fungus mycelium which penetrate the wood or the fruiting body the mushroom or both may be luminous.

The luminous bacteria are so small that individuals cannot be seen by their own light whereas natural colonies are easily visible. They may be cultured on artificial media and form excellent material for the experimental study of bioluminescence. They are not pathogenic to man but are known to infect living animals giving rise to a natural luminescent disease of sand fleas, shrimps and possibly mudges which is eventually fatal. Luminous bacteria may also live symbiotically in definite organs of fish notably *Photoblepharon* and *Anomalops* of the Banda islands. Some believe that the luminescence of all luminous animals even the firefly, is due to symbiotic luminous bacteria but this is far from

proven. The characteristic of the light of bacteria and fungi which distinguishes them from all other luminous organisms is its uniformity shimmering and fading independent of stimulation. Other animals glow only when disturbed or stimulated.

Phosphorescence of the sea is largely due to Protozoa of which the Radiolaria, Dinoflagellata and Cystoflagellata (including *Noctiluca*) are luminous. The latter two groups may develop in such enormous numbers that the sea is a pink or red by day and a vivid sheet of flame by night. Larger patches of light in the ocean are mainly due to coelenterates, jellyfish, Siphonophora or Ctenophora (comb jellies). The latter are often very abundant and show the interesting phenomenon of loss of luminescence in unlight or on bright illumination by electric light. The luminescence again appears on stimulation after about one half hour in the dark. The coelenterates contain more luminous species than any other group, the sea pens or pennatulids showing especially brilliant luminescence which travels along nerves over the colony of polyps in the form of a wave.

Among the Crustacea, Copepoda and Ostracoda (Cypridina) contain many luminous forms while the schizopod and decapod shrimps possess members with true luminous organs or photophores often consisting of lens, reflector and pigment screens, ventable lanterns on a microscopic scale, earlier mistaken for eyes.

Among the worms many marine forms and some earthworms are luminous. Among the echinoderms only the brittle stars (Ophiuroids) possess luminous members.

Luminous molluscs are represented only by *Pholas dactylus* (a bivalve) and *Phyllorhoe bucephala* (a nudibranch) together with the cephalopods of which many members produce light. The cephalopods and deep sea fish possess the most complex lantern like luminous organs.

Some centipedes are luminous as well as the spring tail larvae of the fly *Bohtophila* which live in New Zealand caves and beetles (fire fly glow worm and *Pyrophorus* of the West Indies). All stages including the egg of some fire flies are luminous.

*Balanoglossus* and *Pyrosoma* primitive chordates are also luminous. The latter forms large colonies floating near the surface of the sea, each individual possessing two luminous spots.

Finally mention should be made of the fish, both elasmobranchs and teleosts, containing luminous members. The deep sea forms are often bizarre in appearance and sometimes contain the luminous organ on the end of a long process dangled before the animal as a lure for prey.

The sponges, Alcyonaria, Bryozoa, mayflies, termites, spiders and Salpae contain reported luminous forms whose light production is however doubtful. The light of many phosphorescent animals is not produced by the animals themselves but by symbiotic micro organisms.

In general luminous organs or regions are glandular and the luminous material may be ejected (extracellular luminescence) as a slime or a secretion which in the squid *Heteroteuthis dispar* surrounds the animal in the sea water as does the black ink of other squids. Or the luminous material may be consumed within the photogenic cells (intracellular luminescence) as in the fire fly and organisms possessing photophores. There is always a mechanism for supplying the organ with abundant oxygen, a fact which indicates that the light production is an oxidation.

**Chemical Nature of Bioluminescence.**—Knowledge of the chemical nature of bioluminescence has proceeded in four steps: (1) R. Boyle (1667) showed that fungi and bacteria required air (oxygen) for luminescence, becoming dark under an air pump and luminescing again when air was readmitted.

(2) Reaumur (1733) and Spallanzani (1794) showed that water was necessary; that luminous cells could be dried and preserved in some cases indefinitely producing light whenever moistened. This fact proves also that bioluminescence is not a process involving definite structural peculiarities of the cell as is the contraction of a muscle or the conduction of a nerve impulse which will not occur after drying and moistening.

(3) Dubois, in 1887, found that the photogenic material could be separated into two constituents, luciferin and luciferase, due to marked difference in chemical behaviour. The latter is destroyed

on boiling and behaves like an enzyme or catalyst, the former is heat resisting and the oxidizable body. The substances can be treated like any other chemical compound, precipitated by certain reagents and redissolved in appropriate solvents. They have been partially purified but their chemical composition is still unknown. Their isolation and synthesis is a matter of time and material.

(4) Harvey (1918) showed that luciferin after oxidation to oxyluciferin could be reduced again, that the luminescent process was reversible and of the nature of an oxidative dehydrogenation. It seems most probable that many organisms reduce the oxyluciferin formed during luminescence and thus reutilize the material again and again, a principle that may in time be adopted in industry as the basis of an efficient method of illumination.

Bioluminescence is often spoken of as 'cold light'. This does not mean that no heat is produced but only that very little appears as compared with the ordinary methods of illumination which depend on the incandescence of carbon particles in flames or of wire through which a current is passing. The rise of temperature in some luminous animals is less than 0.001°C. The light is no different physically from any other kind of light—it will affect a photographic plate, can induce chemical reactions and can be polarized. There are no infra red or ultra violet radiations and no penetrating radiations are produced. Hence the luminous efficiency is the percentage of the radiant energy which is visible, is very high, nearly 100%. This does not tell however what the radiant efficiency is, the percentage of the energy (chemical) of the oxidation process which appears as radiant energy, nor does it tell the overall efficiency, the energy (chemical) in the food of the animal which appears as visible radiant energy. This is the efficiency in which an illuminating engineer is interested and studies on luminous bacteria have shown that the overall efficiency of these forms is at least slightly and probably considerably greater than that of a nitrogen filled incandescent lamp when calculated from the energy of the coal necessary to run the dynamo that supplies current to the lamp.

**The Uses of Luminescence.**—Regarding the use of luminescence to the animal little can be said with certainty. In deep sea forms living in perpetual darkness it would seem that the organs must be lanterns for seeing or recognition or for attracting prey. Many luminous forms live in light places and it has been suggested that the luminescence may be a warning to scare away predacious animals which might molest the luminous forms or a lure to attract creatures upon which the luminous animal feeds. These suggestions remain to be proven but we do know that in the fire fly the light acts as a signal or attraction to bring the sexes together. On the other hand who can suggest the use of light to a luminous bacterium, an organism  $\frac{25}{1000}$  in diameter with no nervous reactions of a higher form or the use to a protozoan living at the surface of the sea blown hither and thither by the wind? One is forced to the conclusion that in their case the light is merely fortuitous, a chance phenomenon accompanying some of the chemical changes in the organism.

It is well known that many substances produce light on slow oxidation (chemiluminescence) and the whole process of light production by luminous organisms can be so perfectly imitated by such reactions in the laboratory that we may no longer consider it a mysterious or unusual phenomenon.

## PHYSICAL PROPERTIES

**Allotropic Forms**—The allotropic forms of phosphorus

are the white and violet. The white is the stable form at ordinary temperatures. It is a soft, waxy solid, and is soluble in carbon disulphide and carbon tetrachloride. The violet form is formed by heating white phosphorus at 250°C. It is a dark, crystalline solid, and is insoluble in carbon disulphide and carbon tetrachloride. The red form is formed by heating white phosphorus at 250°C. It is a dark, crystalline solid, and is insoluble in carbon disulphide and carbon tetrachloride. The black form is formed by heating white phosphorus at 250°C. It is a dark, crystalline solid, and is insoluble in carbon disulphide and carbon tetrachloride.

It is also obtained by heating white or red phosphorus for long periods at high temperatures the proportion of violet phosphorus increasing with time and temperature. This fact together with the circumstance that the density of red phosphorus continually increases with the duration and intensity of its heating suggests that the red form is only an intermediate stage in the production of the violet (See above). The variety forms lustrous heavy nearly black minute rhombohedra. A scarlet form was obtained by R. Schenk in 1905 and in 1911 P. W. Bridgman described a black graphitic variety which was obtained by heating ordinary phosphorus at 200°C under a pressure of 12,000 atmos and which was incombustible very dense and conducted electricity. Bridgman obtained also another modification of white phosphorus with a transition point at -76.9°C under atmospheric pressure. The relationships of these forms to white and violet phosphorus are indefinite. The various forms are probably polymorphs for the red phosphorus is at least as complex as  $P_8$  whereas the white is  $P_4$ . Smits postulates two forms  $P_{\alpha}$  and  $P_{\beta}$  as the basis of all varieties and as many of the conversions are very slow the equilibria involved are probably complex.

**Phosphine** (phosphoretted hydrogen)  $PH_3$ , a gas formed in the putrefaction of organic matter containing phosphorus was first obtained (Gengembre 1789) by the action of potash on phosphorus this was spontaneously inflammable whereas Davy obtained a hydride which was not spontaneously inflammable by heating phosphorous acid. In 1855 Le Verrier showed that the two gases were essentially identical and that the inflammability was due to traces of another hydride  $P_2H_4$ . When caustic alkalis are boiled with phosphorus the impure gas is obtained and it also results from the action of water on calcium phosphide (unless this is very pure) but the pure  $PH_3$  may be obtained by heating phosphonium iodide with caustic potash. It is a colourless very poisonous gas with an offensive odour like that of rotting fish it can be liquefied at -86°C and solidified at -133°C. It is only slightly soluble in water burns with a luminous flame fires spontaneously in air at about 100°C and combines violently with oxygen and the halogens. When passed over heated metals it liberates hydrogen and forms the phosphide. It forms double compounds such as  $PH_3 \cdot 2BF_3$  and  $2PH_3 \cdot SiCl_4$  gives phosphonium salts,  $PH_4X$ , with the halogen acids and decomposes to its elements when heated out of contact with air. The hydride  $P_2H_4$  can be condensed as a liquid if the impure gas (above) is passed through U tubes in a freezing mixture. It boils at 57°-58°C, and above

The element is highly inflammable taking fire in air at 34°C burning with a bright white flame and forming dense white clouds of phosphoric oxide. H. B. Baker has shown however that in perfectly dry air or oxygen it can be distilled unchanged (See DRYNESS CHEMICAL). When exposed to air which has not been excessively dried a stick of phosphorus undergoes slow combustion as shown by the phosphorescence visible in the dark. In pure oxygen however this phosphorescence is not exhibited unless the gas pressure is reduced or the temperature raised similarly in compressed air the phosphorescence ceases when a certain pressure is reached. Moreover the presence of certain substances (e.g. Cl, Br, I,  $NH_3$ ,  $N_2O$ ,  $NO_2$ ,  $H_2S$ ,  $SO_2$ ,  $CH_4$ ,  $C_2H_4$ ) entirely inhibits the phosphorescence. During the process oxygen is slightly ionized and traces of ozone are formed. Some of the phenomena accompanying phosphorescence have been ascribed to the oxidation of the trioxide. A very complete bibliography of investigations is given by W. E. Downey (*J. Chem. Soc.* 1924 15 p 349) and H. J. Emeléus (*ibid.* 1926 p 1336 1927 p 788 1928 p 628) gives a further discussion of the inhibition and of the ultra violet spectrum of the glow. Phosphorus combines directly with the halogens sulphur and selenium and most metals burn in its vapour forming phosphides. When very finely divided it decomposes water giving hydrogen phosphide and when boiled with water it gives hypophosphorous acid in addition, slow oxidation of wet phosphorus yields hypophosphoric acid.

**Modern Processes**—In more modern electrothermal processes calcium phosphate mixed with sand and carbon and fed into a furnace heated by an electric current. At the high temperature the silicon is reduced and displaces phosphoric oxide and forms calcium silicate and the oxide is reduced by the carbon so that the phosphorus vapour and carbon monoxide pass over into a condenser. The white form is a liquid and is run off periodically. Other processes seek to produce calcium carbide simultaneously with phosphorus by using only calcium phosphate and carbon thus obtaining a more valuable by-product. In all cases the phosphorus is cut into sticks either under water or in water cooled pipes.

**Properties**—Perfectly pure phosphorus is a white transparent waxy solid its usual yellowish appearance being due to traces of the allotropic red phosphorus which is formed by exposure to light. At 30°C it is soft and flexible but when cooled it becomes brittle and shows a crystalline fracture. Crystallization from carbon disulphide or sublimation yield large crystals of regular dodecahedra or octahedra but these fire spontaneously unless protected from the air. It is also soluble in sulphur chloride benzene oil of turpentine and liquefied ammonia or sulphur dioxide. It is a non conductor of electricity has density 1.826 at 0°C melts at 44°C and boils at 280°C giving a colourless vapour the density of which corresponds to tetraatomic molecules  $P_4$ . Above 1,500°C the vapour density indicates dissociation to  $P_2$ . The elevation of boiling point of solution of phosphorus in carbon disulphide and the depression of freezing point of solutions in benzene both indicate  $P_4$ .

The element is highly inflammable taking fire in air at 34°C burning with a bright white flame and forming dense white clouds of phosphoric oxide. H. B. Baker has shown however that in perfectly dry air or oxygen it can be distilled unchanged (See DRYNESS CHEMICAL). When exposed to air which has not been excessively dried a stick of phosphorus undergoes slow combustion as shown by the phosphorescence visible in the dark. In pure oxygen however this phosphorescence is not exhibited unless the gas pressure is reduced or the temperature raised similarly in compressed air the phosphorescence ceases when a certain pressure is reached. Moreover the presence of certain substances (e.g. Cl, Br, I,  $NH_3$ ,  $N_2O$ ,  $NO_2$ ,  $H_2S$ ,  $SO_2$ ,  $CH_4$ ,  $C_2H_4$ ) entirely inhibits the phosphorescence. During the process oxygen is slightly ionized and traces of ozone are formed. Some of the phenomena accompanying phosphorescence have been ascribed to the oxidation of the trioxide. A very complete bibliography of investigations is given by W. E. Downey (*J. Chem. Soc.* 1924 15 p 349) and H. J. Emeléus (*ibid.* 1926 p 1336 1927 p 788 1928 p 628) gives a further discussion of the inhibition and of the ultra violet spectrum of the glow. Phosphorus combines directly with the halogens sulphur and selenium and most metals burn in its vapour forming phosphides. When very finely divided it decomposes water giving hydrogen phosphide and when boiled with water it gives hypophosphorous acid in addition, slow oxidation of wet phosphorus yields hypophosphoric acid.

this temperature it breaks down to  $\text{P}_2\text{H}_4$  which at once when it is exposed to light or air in contact with hydrochloric acid. The hydric  $\text{P}_2\text{H}_4$  is solid substance which is the product of phosphorus trichloride on PH or on the phosphorus diiodide.

#### PHOSPHONIC SALTS AND OXIDES

**Phosphonium Salts**—The colorless  $\text{PH}_4\text{Cl}$  large transparent cube can be obtained by direct combination of phosphine and hydrogen chloride at  $-30^\circ\text{C}$  but decomposes on rise of temperature. The bromide may be prepared similarly or by heating phosphorus with hydrobromic acid at  $110^\circ\text{C}$  in sealed tubes. It is unstable in air and is decomposed by water. The iodide is readily obtained by mixing phosphorus and iodine in carbon disulphide in a retort distilling off the solvent adding the requisite quantity of water and subliming the iodide.

Caustic alkali or more water decomposes it to phosphine and iodide or hydriodic acid.

Just as amines ( $\text{q.v.}$ ) are derivatives of ammonia so phosphine gives rise to primary secondary and tertiary phosphines and organic phosphonium bases correspond to phosphonium salts. The primary and secondary phosphines  $\text{RPH}$  and  $\text{R}_2\text{PH}$  are formed when alkyl iodides are heated with phosphonium iodide and zinc oxide to  $150^\circ\text{C}$  the reaction mixture is treated with water whereby the primary phosphine is obtained and the secondary phosphine is liberated from its hydriodic by caustic soda. The tertiary phosphines and quaternary phosphonium salts are formed by the same reaction at higher temperatures ( $180^\circ\text{C}$ ) and without the use of zinc oxide. The primary and secondary phosphines are colourless liquids (except methylphosphine which boils at  $-14^\circ\text{C}$ ) of unpleasant odour they react neutral but form salts with acids and are often spontaneously inflammable. Nitric acid oxidizes them to mono and dialkylphosphinic acids respectively  $\text{RPO(OH)}$  and  $\text{R}_2\text{PO(OH)}$ . The tertiary phosphines tend to give derivatives of quinquivalent phosphorus and therefore readily form addition compounds and are oxidized to phosphine oxides  $\text{R}_3\text{PO}$ . The quaternary phosphonium salts resemble the corresponding nitrogen compounds being stable towards aqueous alkalis but converted by digestion with moist silver oxide to the very strongly alkaline phosphonium hydroxide on heating they decompose to the phosphine oxide and a hydrocarbon.

The alkylphosphinic acids are colourless crystalline compounds readily soluble in water or alcohol and dibasic whereas the dialkylphosphinic acids are monobasic.

**Oxides**—Three oxides are well defined viz  $\text{P}_4\text{O}_6$ ,  $\text{P}_2\text{O}_4$ ,  $\text{P}_4\text{O}_{10}$  others (e.g.  $\text{P}_4\text{O}$  and  $\text{P}_2\text{O}$ ) have been described and also disputed. **Phosphorus oxide**  $\text{P}_4\text{O}_6$  is a product of the limited combustion of phosphorus in air if the element is burned in a hard glass tube and a rapid current of air is passed over it the oxide may be condensed in a metal condenser and removed later by warming it. It sublimes in feathery crystals and melts at  $173^\circ\text{C}$  to a colourless mobile liquid of sp gr 1.936 and boiling point  $173^\circ\text{C}$ . Vapour density determinations indicate the formula  $\text{P}_4\text{O}_6$  above about  $300^\circ\text{C}$  in a sealed tube it decomposes to phosphorus and the tetrachloride. It is slowly oxidized by air and rapidly by oxygen (with inflammation at  $10^\circ\text{C}$ ) to phosphoric oxide with cold water it slowly gives phosphorus acid but with hot water it reacts violently forming phosphorus phosphine phosphoric acid and other products. Hot alkalis decompose it similarly but cold dilute alkalis form phosphites. Chlorine or bromine converts it chiefly to  $\text{POCl}_3$  or  $\text{POBr}_3$  whereas iodine forms the diiodide  $\text{P}_2\text{I}_4$  and  $\text{P}_4\text{O}_{10}$ . Hydrogen chloride and phosphorus pentachloride react with it as follows.

It combines violently with sulphur to give  $\text{P}_4\text{O}_6\text{S}_4$  which sublimes as highly lustrous plates (mp  $102^\circ$  bp  $295^\circ$ ) and which is readily decomposed by water to sulphuretted hydrogen and phosphoric acid. Ammonia reacts to give the diamide  $\text{P(OH)(NH}_2)_2$  and its ammonium salt. Phosphorus oxide has a peculiar garlic like odour and is very poisonous the odour and toxicity of phosphorus

phosphorus oxide is probably due to this oxide. **Phosphorus trioxide**  $\text{P}_2\text{O}_3$  or better  $(\text{PO})_2$  since its molecular complexity is not certain. It is obtained (e.g. of  $\text{P}_2\text{O}_3$ ) as lustrous deliquescent crystals. It is not the anhydride of hypophosphoric acid (see below) or water decomposes it to phosphorus and phosphoric acids. **Phosphorus pentoxide**  $\text{P}_2\text{O}_5$  or  $(\text{PO}_2)_2$  (loosely termed pentoxide)  $\text{P}_2\text{O}_5$  is a white powder which sublimates to transparent monoclinic crystals. It reacts violently with water and can be reduced to the element by heating with carbon.

**Acids**—Hypophosphorous and hypophosphoric acids  $\text{H}_3\text{PO}$  and  $\text{H}_4\text{P O}_6$  (or  $\text{H}_4\text{P O}_7$ ) have no known anhydrides. Phosphorous acid  $\text{H}_3\text{PO}_3$  is derived from  $\text{P}_4\text{O}_6$  meta pyro and ortho phosphoric acids are derived from  $\text{P}_4\text{O}_{10}$  and are described under PHOSPHATES. Perphosphoric acids  $\text{H}_5\text{PO}_4$  and  $\text{H}_6\text{P O}_8$  are also known. **Hypophosphorous acid**  $\text{H}_3\text{PO(OH)}$  is prepared as its barium salt by boiling phosphorus with barium water removing excess of barium by passing in carbon dioxide and crystallizing the nitrate. If this salt is decomposed by the calculated amount of dilute sulphuric acid the pure acid can be obtained by careful evaporation of the nitrate under reduced pressure as white crystals melting at  $65^\circ\text{C}$ . It is a monobasic acid and is slowly oxidized in air on heating it gives phosphine and phosphoric acid. It is usually sold as a solution of sp gr 1.37 (about 3%) which is fairly stable. When warmed with copper sulphate solution it produces a red precipitate of the hydride  $\text{Cu}_2\text{H}$  thus demonstrating its exceptionally strong reducing properties its salts are also effective reducing agents. **Phosphorous acid**  $\text{H}_3\text{PO(OH)}_2$  is formed from its anhydride  $\text{P}_4\text{O}_6$  or by passing chlorine into melted phosphorus covered with water the phosphorus trichloride being decomposed *in situ*. The crystals melt at  $10^\circ\text{C}$  are very deliquescent and oxidize in the air on heating they give phosphine and phosphoric acid. It is an energetic reducing agent and although normally dibasic it gives rise to organic esters of the type  $\text{R}_3\text{PO}_3$ .

**Hypophosphoric acid**  $\text{H}_4\text{P O}_6$  or  $\text{H}_2\text{P O}_3$  occurs among the products of oxidation of phosphorus in moist air or in water the solution is neutralized by sodium carbonate and the sparingly soluble lead salt is made and then decomposed by hydrogen sulphide sticks of phosphorus immersed in copper nitrate solution are also oxidized to this acid by means of nitric acid. The aqueous solution of the free acid is stable but it decomposes on concentration unless this be done in a vacuum in which case the hydrate ( $\text{H}_4\text{P O}_6 \cdot 2\text{H}_2\text{O}$ ) separates and can be dried below  $50^\circ\text{C}$  to give the acid this melts at  $70^\circ\text{C}$  and decomposes. The solution does not readily act as a reducing agent. Owing to uncertainty as to the constitution formulae such as  $\text{PO(OH)}_2 \cdot \text{O P(OH)}_2$  and  $\text{PO(OH)}_2$  have been proposed an ester  $(\text{CH}_3)_2\text{PO}_3$  is known (Rosenheim 1910) so the salts are probably best regarded as derived from the polymerized acid. Permono and perdi phosphoric acids are obtained from phosphoric anhydride or meta or pyro phosphoric acids and hydrogen peroxide at  $0^\circ\text{C}$  large excess of peroxide favouring the production of the di acid. The salts are also obtained by electrolysis of dipotassium hydrogen phosphate a high anode current density increasing the proportion of the permono salt.  $\text{K}_4\text{P O}_8$  forms good crystals. The two acids differ in their action on iodides the permono acid liberating iodine at once and the other slowly (compare persulphates see SULPHUR).

**Halogen Compounds**—**Phosphorus trifluoride**  $\text{PF}_3$  obtained by direct union of its elements is a colourless non fuming gas which liquefies at  $-10^\circ$  under 20 atmos solidifies at  $-160^\circ$  and boils at  $-95^\circ$ . It is comparatively stable is only slowly decomposed by water and does not attack glass when cold. **Phosphorus pentafluoride**  $\text{PF}_5$  results from combustion of the element or trifluoride in excess of fluorine or from the interaction of arsenic trifluoride and phosphorus pentachloride. It is a colourless fuming gas of bp  $-75^\circ$  and mp  $-83^\circ$  and is dissociated by large induction sparks but not by heat (compare  $\text{PCl}_5$  and  $\text{PBr}_5$ ) it is readily decomposed by water.

Phosphorus is obtained by heating iron pyrites (FeS<sub>2</sub>) in a retort. The sublimate is a colourless solid which melts at 44.1°C. It is a powerful oxidizing agent and is used in the manufacture of matches, incendiary bombs, and in the production of phosphoric acid. It is also used in the treatment of certain diseases, such as syphilis and leprosy. Phosphorus is highly flammable and should be handled with care. It is usually stored under water to prevent oxidation.

Phosphorus pentachloride (PCl<sub>5</sub>) is a colourless liquid which boils at 130.5°C. It is used in the synthesis of various organic compounds, particularly in the preparation of phosphorus esters and amides. It is also used in the production of phosphoric acid and in the treatment of certain diseases.

Phosphorus trichloride (PCl<sub>3</sub>) is a colourless liquid which boils at 76.1°C. It is used in the synthesis of various organic compounds, particularly in the preparation of phosphorus esters and amides. It is also used in the production of phosphoric acid and in the treatment of certain diseases.

$\text{PCl}_5 + \text{H}_2\text{O} \rightarrow \text{HCl} + \text{POCl}_3$   $\text{POCl}_3 + 3\text{H}_2\text{O} \rightarrow 3\text{HCl} + \text{H}_3\text{PO}_4$

The pentachloride is extensively used in organic chemistry, e.g. for replacing hydrogen groups by chlorine.

*Phosphoryl chloride* or phosphorus oxychloride (POCl<sub>3</sub>) may be produced as shown above or by the interaction of phosphoric oxide on the pentachloride or on hydrogen chloride.

It is a colourless liquid of b.p. 105°C and m.p. -133°C with water it gives hydrochloric and phosphoric acids with dilute alcohol (ethylphosphoric acid, CH<sub>3</sub>CH<sub>2</sub>PO<sub>4</sub>) and with absolute alcohol triethyl phosphate, PO(OC<sub>2</sub>H<sub>5</sub>)<sub>3</sub>. *Pyrophosphoryl chloride* (P<sub>2</sub>O<sub>5</sub>Cl<sub>4</sub>) is also known. *Thiophosphoryl chloride* (PSCl<sub>3</sub>) is formed by direct combustion of sulphur and PCl<sub>3</sub> by the action of sulphurated hydrogen, antimony trisulphide or phosphorus pentasulphide upon P<sub>4</sub>O<sub>10</sub> or by dissolving phosphorus in sulphur chloride and distilling:  $2\text{P} + 3\text{SCl}_2 \rightarrow 4\text{S} + \text{PSCl}_3$ . It is a colourless liquid (b.p. 15°C) is decomposed by water to acids corresponding to each of the three elements and gives thiophosphates with alkalis, e.g.  $\text{PS}(\text{OK})_2$ .

*Phosphorus tribromide* (PBr<sub>3</sub>) prepared by passing bromine vapour (diluted with carbon dioxide) over phosphorus or by mixing solutions of the two in carbon disulphide and distilling is a liquid boiling at 115°C and resembling the trichloride chemically. The *pentabromide* (PBr<sub>5</sub>) resulting if an excess of bromine is used in the above preparations is a yellow solid closely resembling the pentachloride. *Phosphoryl bromide* (POBr<sub>3</sub>) (m.p. 45°C, b.p. 195°C) and *thiophosphoryl bromide* (PSBr<sub>3</sub>) (m.p. 38°C) both resemble the corresponding chloro compounds. The action of iodine and phosphorus when dissolved in carbon disulphide (free from sulphur) gives rise to a *diiodide* PI<sub>2</sub> or P<sub>2</sub>I<sub>4</sub> (m.p. 124°C) a *triiodide* PI<sub>3</sub> (m.p. 61°C) and possibly a *subiodide* P<sub>4</sub>I<sub>6</sub>.

#### SULPHUR AND NITROGEN COMPOUND

**Sulphur Compounds.**—Phosphorus and sulphur combine energetically to form a series of sulphides three of which are well defined viz. P<sub>4</sub>S<sub>3</sub>, P<sub>4</sub>S<sub>7</sub> and P<sub>4</sub>S<sub>8</sub> (see A. Stock, *Berichte* 1908 et seq.) the first is sometimes used as a substitute for phosphorus in matches and the last finds application in organic chemistry for replacing oxygen by sulphur. There is also evidence for the existence of P<sub>2</sub>S<sub>6</sub>, P<sub>2</sub>S<sub>5</sub> and possibly P<sub>2</sub>S<sub>4</sub>. Thiophosphates (e.g. Na<sub>2</sub>PSO<sub>3</sub> and Na<sub>2</sub>PS<sub>2</sub>O<sub>2</sub>) result from the dissolution of P<sub>2</sub>S<sub>5</sub> in alkalis whereas by melting it with the sulphides or chlorides of heavy metals salts analogous to Na<sub>2</sub>PS<sub>4</sub> are obtained which are somewhat unstable in water and still more so towards acids.

**Nitrogen Compounds.**—Phosphorus pentachloride reacts readily with ammonia to give PCl<sub>3</sub>·5NH<sub>3</sub> and thence PCl<sub>3</sub>(NH<sub>2</sub>)<sub>2</sub> chlorophosphamide which is decomposed by water to PO(NH<sub>2</sub>)<sub>3</sub>.

(NH<sub>2</sub>)<sub>3</sub> or heated to phosphorus (NH<sub>2</sub>)<sub>3</sub> a white insoluble solid which when PO(NH<sub>2</sub>)<sub>3</sub> is heated gives phosphoryl amide (O=P(NH<sub>2</sub>)<sub>3</sub>). When phosphorus pentachloride reacts with ammonia it gives phosphorus pentachloride (PCl<sub>5</sub>) which reacts with water to give phosphoric acid (H<sub>3</sub>PO<sub>4</sub>). The reaction of phosphorus pentachloride and ammonia chloride is a useful method for producing phosphorus pentachloride (PCl<sub>5</sub>) which is used in the synthesis of various organic compounds.

**Therapeutics and Toxicology.**—Various preparations of phosphorus are used in the British Pharmacopoeia. The element is used for the growth of bones in our animals and hence compounds are used in medicine. It is also efficient as a nerve tonic in cases of agitated locomotor ataxia, impotence and nervous exhaustion. In some skin diseases such as psoriasis, chronic eczema and acute indurata phosphorus is useful. The hypophosphites are recommended in pulmonary affections and are used in tonic and the glycerophosphates stimulate metabolism. Dilute phosphoric acid is used as a gastric stimulant.

Phosphorus is readily accessible in poisonous forms, e.g. in vermin poisons and some matches and is often taken either intentionally or accidentally. Symptoms of acute poisoning are usually shown after some delay with nausea, vomiting and burning sensations in the oesophagus, stomach and abdomen. Emetics and purgatives should be given at once to prevent absorption of the poison. Doses of 3–5 grains of copper sulphate in water at intervals of a few minutes form the harmless copper phosphide. The stomach should be washed out with warm water and then with a 1% solution of potassium permanganate and this solution should also be given as an enema. Oils which are effectual in other cases of irritant poisoning should not be given for they tend to dissolve phosphorus and retain it in the system. The old French oil of turpentine however acts as an antidote in allaying the toxic effects. When yellow phosphorus was used in matches those engaged in the manufacture used to suffer from a form of necrosis called phossy jaw in England the red form now employed is however non-poisonous. (A. D. M.)

**PHOTIUS** (c. 850–891) patriarch of Constantinople (858–867 and 878–886). The way to public life was probably opened for him by the marriage of his brother Sergius to the princess Irene, sister of Theodora, who upon the death of her husband Theophilus in 842 had assumed the regency of the empire. Photius became captain of the guard and subsequently first imperial secretary. The dissensions between the patriarch Ignatius and Bardas, the uncle of the youthful Emperor Michael III, brought promotion to Photius. Ignatius was arrested and imprisoned (Nov. 858) and upon refusing to resign his office was illegally deposed while Photius, although a layman, received all the necessary sacerdotal orders within six days and was installed as patriarch in his place. Ignatius, continuing to refuse the abdication which could alone have given Photius's elevation a semblance of legality, was treated with extreme severity. His cause was subsequently espoused by Pope Nicholas in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions and when in 867 Nicholas finally anathematized and deposed him, he replied by a counter excommunication. Meanwhile the situation was suddenly changed by the murder of Photius's patron Bardas by order of the emperor Michael who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued; he was removed from his office and banished about the end of September 867 a few days after the accession of Basil and Ignatius was reinstated on Nov. 23.

About 876 Photius was suddenly recalled to Constantinople and entrusted with the education of Basil's children. On the death of Ignatius, probably in October 878, Photius again became patriarch. In 879 the legates of Pope John VIII attended a synod convened at Constantinople prepared to acknowledge Photius as legitimate patriarch, a concession for which John was

much concerned by Latin origin. P. Johr. continued his studies in the curriculum of Photius. Photius ignored John's action but a police resolution caused his banishment (186) to Bardi in Calabria. He died there on Feb. 6, 801.

Photius, who is to no little extent named as an ecclesiastic's agent in the 9th century, was heroic in his activity, profound and far-seeing. He supported good and evil for one with equal dignity and his fall was on both occasions due to revolutions beyond his control. In erudition, literary power and force and versatility of intellect he surpassed every contemporary.

The most important of the works of Photius is his renowned *Bibliotheca* or *Myriobiblon* (ed. I. Bekker 1844-1855), a collection of extracts from and abridgment of 280 volumes of classical authors (usually cited as *Codices*) the originals of which are now to a great extent lost. To Photius we are indebted for almost all we possess of Ctesias, Memnon, Conon, the lost books of Diodorus Siculus and the lost writings of Arrian.

The *Lexicon* (*Λεξικόν*) was probably in the main the work of some of his pupils. The only ms. of the *Lexicon* is the Codex Galeanus at Trinity College, Cambridge (ed. S. A. Naber 1864 with introduction on the authorities, critical commentary and valuable indexes). The *Amphilochia* is a collection of some 300 questions and answers on difficult points in Scripture addressed to Amphilochius, archbishop of Cyzicus (ed. Sophocles Oeconomus Athens 1858). Other similar works are his treatise in four books against the Manichaeans and Paulicians and his controversy with the Latins on the Procession of the Holy Spirit. His *Epistles* were edited by J. Valettas (London 1864). A large number of his speeches and homilies have been edited by S. Anastarches (1900). The only complete edition is Bishop Malou's in Migne's *Patrologia graeca* c. c. v. R. Reitzenstein (*Der Anfang des Lexikons des Photius* 1901) has published a hitherto unedited ms. containing numerous fragments from various verse and prose authors.

See Cardinal Herenrother *Photius, Patriarch von Constantinopel* (1867-69).

**PHOTOCHEMISTRY** is that division of physical chemistry which deals with the chemical action of radiant energy on matter and with the direct production of radiation by chemical reactions. The field of photochemistry might be regarded as being equally as extensive as the range of electromagnetic vibrations from the tiny ultra X rays to the huge waves of wireless. Actually limitations exist and photochemical reactions are considered primarily as the transformations of matter associated with radiations between and including the trans ultra violet and infra red radiations. This range includes the visible radiations and a band on either side of approximately the same width as that covered by the visible radiations. The wave lengths included are those between  $10\mu\mu$  and  $1000\mu\mu$ . The micron  $\mu$  a measure of length is  $10^{-4}$  cm or  $10^{-3}$  mm and the millimicron  $\mu\mu$  is  $10^{-7}$  cm or  $10^{-6}$  mm. The direct production of radiation by chemical reaction is termed *chemiluminescence*. It is differentiated from the radiation produced in such reactions as combustion by the absence of thermal equilibrium between the matter and the radiation concerned (see RADIATION).

**Principle of Photochemical Equivalence**—Previous to about 1910 photochemistry had but one accepted generalization the *absorption law* according to which only the light energy absorbed by a body is active in promoting chemical change. This is a special case of the principle of conservation of energy which states that energy may be neither created nor destroyed. Nearly a century after the first expression of this law a principle of photochemical equivalence was put forward in 1922 by A. Einstein. It is founded on Planck's quantum theory (see QUANTUM THEORY) of radiation according to which all exchange of energy as radiation between atoms and molecules takes place discontinuously by quanta of finite magnitude  $\epsilon = h\nu$  where  $\nu$  is the frequency of vibration,  $h$  a universal constant equal to  $6.55 \times 10^{-27}$  ergs/sec.  $\epsilon$  varies continuously in magnitude with the multiplying frequency  $\nu$  but Planck's  $h$  is an invariable quantum of action.

The photochemical equivalence principle of Einstein states that in a primary photochemical process the decomposition of one molecule requires one quantum of energy  $h\nu$ , or that one gram molecule requires  $Nh\nu$ , where  $N$  is Avogadro's number of gas molecules per litre,  $6.06 \times 10^{23}$ . In his original derivation he

proposed a reversible reaction of simple unimolecular decomposition

the bimolecular reaction involving the chemiluminescent reaction of the carbon vapor supposed to occur in a gaseous or dilute form. In later deduction this primary photochemical event appeared to be limited to the excitation of an atom or molecule

the atom or molecule  $C$  being raised to a higher energy level. It may be stated at once that this generalization is not so complete or sufficient that all photochemical phenomena can be interpreted by its sole aid. It has none the less completely changed the outlook, beside leading to improvements in the technique.

**Experiment and Technique**—Modern investigation of a photochemical reaction essentially involves determining its quantum efficiency in the sense of Einstein's principle. This requires certain elements of technique—(a) a light source of sufficient intensity adequately monochromatized, (b) exact measurement of the energy absorbed during a given reaction period, (c) distinction of the primary photochemical reaction if possible from secondary dark reactions, (d) determination of the molecular order of the reaction involved and analytical measurement of the product of the photochemical reaction proper.

As to the first there are not many available reactions occurring in light of the visible spectrum range. As visibility coincides fairly closely with the spectral distribution of energy in sunlight—a matter of natural selection—it is obvious that on the whole only systems stable in such illumination will be readily found. Much more frequent are photochemical reactions in the ultra violet and artificial light sources rich in these rays are most used in laboratory research as well as for certain industrial applications. The ultra violet radiation from electric glow lamps is relatively feeble and does not extend far to the shorter waves. Research has to be made to spark and arc discharges. The latter are generally more convenient. The three chief types used may be described as carbon arcs, magnetite and high melting metal arcs as tungsten arcs and metal vapour arcs of these the mercury vapour arc in fused quartz is the most important. The spectrum is discontinuous and it is not difficult to secure approximately monochromatic light at several different wave lengths by the use of colour screens or ray filters. Unfortunately when the far ultra violet rays are in question ( $\lambda$  less than  $100\mu\mu$ ) there are no very satisfactory filters available the best requiring the use of chlorine and bromine gases. When a high degree of monochromatic purity is required the light must be dispersed and quartz monochromators employed with great reduction of intensity. With regard to the other requirements the measurement of the energy absorbed in a reaction is determined with a radiometer (*qv* such as a thermopile radiometer or bolometer) as the difference between the energy incident upon and transmitted through the reaction mixture the latter is usually contained in a vessel with plane parallel quartz walls and maintained at constant temperature. The distinction of the primary photochemical reaction, the determination of the molecular order and of the quantum efficiency are then matters of interpreting the analytical results for different periods of the reaction.

The fundamental researches on photochemical equivalence were those of E. Warburg. They occupy in the modern era of photochemistry somewhat the position of the classical photochemical investigations by Bunsen and Roscoe in preceding years. Warburg introduced a convenient term the *quantum efficiency*, this is the ratio of the effective photochemical equivalent  $\phi$  to the ideal photochemical equivalent  $P$ . Both  $\phi$  and  $P$  are expressed in terms of the number of gram molecules absorbing and decomposed by one gram calorie of radiation of frequency  $\nu$ . When Einstein's law holds  $\phi/P = 1$ . Tabulated results of several reactions show that relatively few reactions confirm the Einstein relation among which are some for which the efficiency is actually less than unity but which give this value when extrapolated back to the start of the reaction. This procedure is justifiable when a

\_\_\_\_\_

A difficulty of exactly the opposite kind for the primary decomposition of the molecule developed from the investigations of physicists on the energy required to make gas molecules fluoresce. It was shown that at low pressures a molecule of gas can take up many times its heat of formation without decomposing. For example iodine,  $I_2$  can absorb and re-emit as resonance radiation an amount of energy five times its heat of formation. On the modern theory of atomic and molecular struc-

En 0407-Per of our - Lie of a ord  
replacement

**The Dissociation of the Molecule**—In the gaseous or independent state molecules may be classed as heteropolar and homopolar or non polar (*see* ELECTROLYSIS) the former having large electrical moments. In the homopolar molecules no such electrical dissymmetry appears. However not only are molecules of all sorts of intermediate type known but the polarity of one and the same molecule depends on its environment. If a heteropolar molecule such as HBr absorb energy the increase of oscillation energy is small. An electron of the positive ion is raised to a higher quantum state thereby inducing stronger not weaker binding and no dissociation *e.g.* into positive and negative ions can be expected from the absorption of light. It is not impossible however that an electron should be removed from the anion by radiation although spectra corresponding to the reaction

In homopolar molecules Franck suggests two types of linkage. In one electrons are shared in common (covalency)  $e \frac{1}{2}$  in  $H_2$  and  $O_2$  such molecules cannot separate from the normal state adiabatically into two atoms and the electron jumps associated with the formation and dissociation of these molecules cannot be produced by radiation processes but only through collision. In agreement with this no point of convergence of bands has been observed in the molecular spectrum of hydrogen. A second type of homopolar linkage is however of much smaller strength—sometimes termed van der Waals forces,  $\frac{1}{2}e$ , akin to the attraction between gas molecules and the chemist's residual affinity operative in molecular association. Here the molecule may take up so much oscillation energy through absorption that it will separate into a normal and an excited atom. There is evidence that the halogen molecules belong to this class. The absorption

FIG 1—DIAGRAM SHOWING HOW PHOTOCHEMICAL YIELD SHOULD INCREASE WITH WAVELENGTH

spectrum of iodine which is diagrammatically represented in figure 2. It indicates that the shorter wavelength the smaller the interval between the oscillation quanta until a real convergence limit appears at about 5000 Å with strong continuous spectrum beyond. The Angstrom unit 1 Å = 10<sup>-10</sup> cm = 10<sup>-8</sup> cm. Bromine and chlorine also have continuous spectra of known wavelength limits 5000 Å for Br and 4500 Å for Cl. This con-

FIG. 2—DIAGRAMMATIC REPRESENTATION OF A PORTION OF THE ABSORPTION SPECTRUM OF IODINE

vergence limit seems to be critical for dissociation of the molecule and it may be assumed that *absorption of light of wave length equal to or shorter than these convergence limits of the band spectra will dissociate the molecule into a normal and an excited atom*. Recent work indicates that the absorption spectrum of oxygen O<sub>2</sub> is similar to that of iodine but the continuous spectrum lies at a much shorter wavelength. Furthermore the ultra violet absorption spectra of HBr and HI during photochemical decomposition were found to be continuous. Hence it is concluded that the molecules also are directly dissociated into atoms by light absorbed in this region.

**Types of Photochemical Reaction**—On the basis of comparison of the absorption spectrum with actual photochemical behaviour we have then a very important division of photochemical reactions into two classes (This division was clearly suggested by J. Franck, *Elementary Processes of Photochemical Reactions, Faraday Soc. Symposium* but more explicitly developed by R. H. Gerke, *J. Amer. Chem. Soc.* 19749 p. 2671). In one class the molecule is merely converted by absorption of radiation into an excited molecule

The resultant excited molecule may (a) lose energy by radiation (fluorescence resonance radiation) or (b) lose energy by collision with another molecule in which case a number of things may happen. The most likely is conversion to heat as energy of translational motion. The broadening of absorption lines in gases with pressure and in solutions the reduction of fluorescence by inert gases are evidence of energy damping of this kind. Another possibility however is collision not with an indifferent molecule but with an acceptor i.e. a molecule capable of reacting with the excited molecule or of itself undergoing chemical change. In all cases where the excited molecule itself appears in the photo product we have what has been conveniently termed (R. H. Gerke *loc. cit.*) the *excited reactant* type of photochemical reaction. Some examples are given in the following table.

Reaction	Absorbing molecule	Type of spectrum	Active radiations Å U	Quanta absorbed per mol of reaction	Heat effect of reaction
O = 2/3 O <sub>3</sub>	O <sub>2</sub>	Band	1970-1756	1.04-3.4	Endothermic
NH <sub>3</sub> = 1/2 N <sub>2</sub> + 3/2 H <sub>2</sub>	NH <sub>3</sub>		260-1515	2-10	Exothermic
O <sub>3</sub> = 3/2 O <sub>2</sub>	O		6700 and uv		
H + 1/2 O <sub>2</sub> = H <sub>2</sub> O (dry)	O <sub>2</sub>		1970-1756		
CO + 1/2 O <sub>2</sub> = CO <sub>2</sub> (dry)	O <sub>2</sub>		1970-1756		
CH <sub>3</sub> CHO + 1/2 O <sub>2</sub> = CH <sub>3</sub> COOH	CH <sub>3</sub> CHO		2800-2350		

Where however the excited molecule does not itself enter into chemical reaction but colliding with another different molecule induces chemical change in this we have an *excited sensitizer* or photocatalysed reaction. The first cases of gas reaction

of this type were discovered by F. Weigert (1907) being a number of reactions in which chlorine gas in light produced decomposition or combination without appearing in the products. A notable example was the sensitized decomposition of ozone by chlorine. Recent experiments on the excitation of mercury vapour in ultra violet light have widened the field of these reactions and helped to clarify their nature. In experiments on the excitation of gas molecules or atoms by electrons of known velocity (voltage) it was found that for a certain velocity of the electron a bombarded atom became excited and emitted radiation of definite wavelength. The velocity of the atom plus electron lost kinetic energy just equal to the quantum radiated. But conversely a slow moving electron colliding with an excited atom might gain kinetic energy the atom becoming normal without radiating. Such collisions are termed *rayless collisions* of the second kind. The same kind of rayless transfer of quantized energy was also found to be possible between atoms and molecules in gases. Cario and Franck showed that mercury atoms excited by the resonance line λ<sub>35</sub> could transfer their excess energy to hydrogen molecules with production of active hydrogen very possibly atomic hydrogen according to the reactions

A considerable number of such mercury sensitized reactions have now been investigated by H. S. Taylor and others. The intermediate active hydrogen has been caused to decompose ethylene C<sub>2</sub>H<sub>4</sub>, carbon monoxide CO forming formaldehyde, solid polymers and methane. Some of these excited sensitizer reactions are here tabulated.

Reaction	Absorbing sensitizer	Type of spectrum	Active radiation Å U	Quanta of radiation per mol of reactant	Heat effect of reaction
H = 2H	Hg	Line	536		Endothermic
O = 3/2 O <sub>2</sub>	Hg		536		Exothermic
H <sub>2</sub> + 1/2 O <sub>2</sub> = H <sub>2</sub> O	Hg		2526		
N <sub>2</sub> O <sub>2</sub> = N <sub>2</sub> O <sub>4</sub> + 1/2 O <sub>2</sub>	N <sub>2</sub> O	Band	4600-4000		Negligible

In both these excited molecule reactions the chemical yield on the photochemical equivalent basis will very probably not agree with the Einstein equivalence principle because the excited molecule may lose energy either by fluorescence or by ineffective collisions. Yet the primary event formation of an excited molecule is itself regulated by the photochemical equivalence. If however the absorbed frequency is equal to or greater than the convergence limit of the band spectrum of the substance absorption takes place with *primary decomposition*

and here the yield is in full agreement with Einstein's law. It appears therefore that when absorption takes place of frequencies still low enough for the atom or molecule to resonate photochemical reaction need only follow indirectly. When however the radiation note is pitched too high for the system to resonate the atom or molecule is shattered.

**Chain Reactions**—In many exothermic photochemical reactions it is found that the photochemical efficiency may be manifold up to 10<sup>6</sup> molecules per quantum absorbed. The most fully studied though still incompletely unriddled example is the union of chlorine and hydrogen in light

In the completest possible absence of water vapour this reaction does not proceed in ordinary and ultra violet light within the band spectrum of chlorine but does so in ultra violet light at

COAL In the reaction of an excited carbon molecule with water vapor, the reaction is exothermic and the products are carbon monoxide and hydrogen.

The reaction is supposed to be not properly understood.

In the presence of very pure even excited molecules can react with each other to form a stable molecular complex must be formed of much higher life than the one usually assigned to excited molecules.

The conception of reaction chains to explain high quantum yields was introduced by M. Bodenstein and developed by W. Nernst. In the type just mentioned implying a primary decomposition reaction a free atom or group is produced. This reacts with one of the original molecules forming another free atom or group and so forth. The process is exhausted by the gradual recombination of the free atoms or groups with each other. In another type an excited molecule is produced which activates a molecule of reactant by collision. This activated molecule then forms another activated molecule of the product and so on. There is therefore a succession of rayless transfers of energy, the chain ceasing again by dissipation of energy in fruitless collisions. It is very possible that in certain cases particularly where water vapour plays a part metastable intermediate molecules or groups are formed.

#### Photochemical Induction Inhibitors and Water Vapour

The classical investigations of Bunsen and Roscoe upon the photochemical union of chlorine and hydrogen revealed the existence of a latent period during which no combination occurred. They regarded this induction as common to all chemical reactions as required for the overcoming of starting friction. Many explanations were offered of photochemical induction until D. L. and M. C. C. Chapman showed it to be due to the presence of specific impurities. These suspend or inhibit the reaction until destroyed by the light or the photochemical change itself. In the hydrogen-chlorine reaction ammonia is an important inhibitor as are the oxides of nitrogen. Oxygen again can function as an inhibitor either by itself accepting hydrogen atoms or by reacting with excited chlorine atoms. In many reactions substances may act as negative photocatalysts simply by absorbing exciting radiation.

In certain gas reactions water vapour may appear as a positive catalyst as for example in the combination of chlorine and hydrogen in visible light. Explanations range from intermediate hydrates (containing active atoms) to facilitation of an action limited to a polar layer on the walls of the reaction vessel.

**Photochemistry and Carbon Compounds.**—The number of organic syntheses and decompositions capable of being effected by light has been greatly increased as more efficient sources of ultra violet light become available. Most of these however remain quantitatively unproved and so far relatively few have become tools for organic synthesis. The most important investigations in this field at present are those concerned with the quantitative measurement and interpretation of absorption spectra (a notable work is V. Henri's *Études de Photochimie* 1915) from which we may anticipate certain approximate inductions on the photochemical reactivity of specific groups (or specific linkages) such as  $>C=O$ ,  $>C=S$ ,  $-C=C-$ ,  $N\equiv C-$  etc. either singly conjugated in chains or condensed. And this may yield a workable knowledge of relations between photochemical reactivity, unsaturation and the life periods of free radicals. Among synthetic reactions the photopolymerizations of vinyl compounds are perhaps the most interesting because of the relations of such bodies to organic high molecular colloids such as the rubber hydrocarbon  $(C_5H_8)_n$ , starch  $(C_6H_{10}O_5)_m$  and cellulose  $(C_6H_{10}O_5)_n$  and eventually proteins  $NH_2(CO NH)_mCOOH$ . There are two organic photolyses of quite dominating impor-

One is the reaction of carbon dioxide with water vapor, the other is the reaction of carbon dioxide with hydrogen. The photochemical reaction of carbon dioxide with water vapor is exothermic and the products are carbon monoxide and hydrogen. The reaction of carbon dioxide with hydrogen is endothermic and the products are carbon monoxide and water.

**Photosynthesis.**—The green leaf is the source of starch which is the result of the photochemical industry of agriculture. It is generally emphasized that photosynthesis is the riddle expressed in the crude equation

Carbon dioxide—Water form Starch—Oxygen

is by no means solved. The *formaldehyde hypothesis* of Beyer extends the production of carbohydrates (starches, sugars, cellulose) by a primary formation of formaldehyde

Carbon dioxide—Water form Formaldehyde—Oxygen

by light in the presence of chlorophyll which is supposed to be followed by a biochemical or photochemical condensation of the formaldehyde

This theory has been strongly supported by B. Moore, D. Berthelot and recently by E. C. C. Baly and severely criticized by H. A. Spoeher whose monograph *Photosynthese* (*American Chem. Soc. Monographs* 1915) furnishes a very complete study of the subject. The issue is of capital importance for chemistry perhaps ultimately for the economy of mankind since it is concerned with the basic process of food production. Baly and his co-workers claim that the reaction

can be effected (a) by ultra violet rays at 2060 Å.U. (b) by sunlight in the presence of dyes such as Malachite Green. They also assert that the condensation of formaldehyde to reducing sugars can be effected by ultra violet rays at 2900 Å.U. More recently Baly has published further evidence supporting the production of alkaloids by direct photochemical synthesis *in vitro*.

Meanwhile the work of other investigators notably O. Warburg, R. Wurms, and H. A. Spoeher following the pioneer efforts of A. Brown and H. Escombe has shown the actual photochemical efficiency of the chlorophyll sensitizer to be fairly high, perhaps up to 80% of an absorbed quantum being converted into stored chemical energy at moderate light intensities. *Chlorophyll*, the chemical constitution of which has been unravelled by the masterly work of R. Willstätter undoubtedly acts as a photochemical sensitizer like the dyes used in photographic processes (*qv*).

**Industrial Prospects.**—The total amount of solar energy incident upon the earth's surface is very great. Taking a solar constant of 1.5 calories per sq. cm. per minute it can be calculated that onto every square mile of the Sahara Desert about 67 billion British Thermal Units of heat are given by the sun in a 6-hour day. The area of this desert is about 2,300,000 sq. miles. If therefore only a minute fraction of this heat could be utilized we should be able to realize the prophetic words of a great chemist (G. Ciamician). The exhaustion of coal will not halt civilization destined to advance as long as the sun shines. Then our sooty and neurotic age of coal will yield to a purer and calmer epoch relying upon solar energy for a fortune and a progress without mischance.

FIG. 1—MILLIKAN'S APPARATUS FOR DETERMINING THE ENERGY OF PHOTOELECTRONS LIBERATED BY LIGHT OF KNOWN WAVELENGTH

not only for it simplicity but also because it introduced Planck's constant  $h$  into a free domain. It was verified later experimentally and shown his theory agreed in its details with Planck's experiments before it was established. O. W. Richardson, K. T. Compton and also A. L. Hughes in their work on the emitted electron did increase proportionally with the frequency and that the constant of proportionality was approximately equal to the value of Planck's constant  $h$  obtained by other means. Subsequently Millikan carried out an extensive series of experiments which established the relation so accurately that it is now considered to give one of the most trustworthy values for  $h$ . This method is typical of the best method of investigation of the photoelectric effect of light and will be described in some detail. The apparatus is shown in fig. 1 and may conveniently be considered in two parts as divided by the dotted line. Cylinders of the alkali metals (sodium potassium lithium) were mounted on an axle in a highly evacuated glass vessel. The actual experiment is carried out by the part of the apparatus to the right of the dotted line light entering through the window and falling on the metal surface. Previous work had shown that reliable results could be obtained only when the metal had a clean fresh surface prepared *in vacuo* and the apparatus on the left of the dotted line consisted of various devices by which the cylinder of alkali metal could be brought opposite the knife which was then operated by an electro magnet outside the tube so as to shave off the outer layer of the alkali metal leaving a fresh uncontaminated surface. Supposing this to be done the cylinder was then rotated to be opposite the window and the actual experiment could begin. A beam of monochromatic light from a spectrometer passed through the window and fell on the prepared surface leading to the emission of electrons which were collected by the gauze cylinder on the right side of the apparatus connected to a quadrant electrometer. If a small positive potential were then applied to the metal block the electrons would arrive at the gauze with lower energies owing to the retarding action of the potential. The maximum energy of emission could thus be measured by finding that positive potential  $V$  which just sufficed to prevent any electrons arriving at the gauze and communicating their charge to the quadrant electrometer. The maximum energy of the electrons is then  $eV$  where  $e$  is the electronic charge. Millikan showed to an accuracy of one half of 1% that with each metal the energy of the emitted electrons varied linearly with the frequency of the light and that in each case the constant of proportionality was the same and equal within the experimental error to the values obtained for Planck's constant by other methods.

**Photoelectric Effect of X rays or  $\gamma$  Rays.**—The essential distinction between the photoelectric effect of X rays or  $\gamma$  rays and that of light lies in the higher frequency of the former radiations and in the correspondingly greater energy of the quantum

The current in the rotor is now measured in tens or thousands of amperes rather than in millivolts and not in terms of the induced EMF. It is to be expected that the current in the rotor will be used to melt the

[illegible]

The general type of apparatus which is used in the investigations is shown in fig. 1. The source of the photoelectrons may be either a thin foil on to which  $\alpha$  rays are fired from outside the box or a wire coated with radioactive material which as will be described later copiously emits photoelectrons. Above the source is a slit which allows a beam of the electrons to pass. This apparatus is placed in an evacuated box between the poles of a large electromagnet and on application of the magnetic field the beam of electrons is bent round into a circular path. By this process it will be analysed into its different velocities since the fastest electrons will describe the largest circle and the slowest electrons the smallest circles. A record of the velocity spectrum of the photoelectrons is obtained by a strip of photographic plate. This is frequently referred to as the focussing method since as can be seen from fig. 2 the rays leaving the source within quite a large solid angle are concentrated in one spot on the photographic plate. A reproduction of a photograph was taken recently in this way by Prof. H. H. Robinson.

This type of apparatus does not give lines sharp on both sides but only on the high velocity side and a series of such lines can be seen on the photograph. These show the various groups of electrons ejected from gold atom by the characteristic  $K\ X$  rays of

FIG 2 — FOCUSING METHOD OF ANALYSING COMPLEX BEAM OF ELECTRONS BY REFLECTION IN UNIFORM MAGNETIC FIELD

copper ( $\text{Cu } K_{\alpha}$ ). On the original photograph it is possible to distinguish no less than 13 groups some of which are partially superimposed. All of these are due to the absorption of the same frequency radiation and the difference in the energies of the groups is due to the multiplicity of the electron levels in gold.

This method was first tried by Robinson and Rawlinson in 1913, and owes its development largely to M de Broglie. Since the frequency of the X rays used is known from crystal measurements, and the energies of the electron groups can easily be ascertained from the geometry of the apparatus and the value of the

magnetic field it has been possible to verify Einstein's law with considerable accuracy. The accurate measurements carried out by Robinson have confirmed the truth of this equation to be at least one part in 300. It would however be emphasized that the importance of the method is that it provides an admirable means of investigating the electron levels in the atom and from the intensities of the photographs it is possible to estimate the probability of absorption of the radiation by each of the separate elements.

Instead of using X rays generated in the usual way it is possible to employ the natural X rays or  $\gamma$  rays emitted by radioactive bodies during their disintegration. These are similar to X rays only in most cases the frequencies and therefore the energies of the quantum are much higher. It was by obtaining photographs by the use of these rays that it was first possible to demonstrate that the  $\gamma$  rays were sharply monochromatic and constituted a true characteristic spectrum of the nucleus. This method is particularly interesting in this connection since it forms the only practicable way of measuring the wave length of  $\gamma$  rays. The ordinary crystal methods of measuring the wave length of X rays are difficult to apply as the wave length is so short and before the photoelectric effect was understood only estimates could be made. By investigating the photoelectrons ejected from various metals by the  $\gamma$  rays Ellis was able to ascertain the particular portion of the atom from which the electrons were being emitted and then a simple measurement of their energies coupled with our X ray knowledge of the atom immediately yielded the  $h\nu$  of the  $\gamma$  rays.

An entirely different method of investigation is rendered possible by C. T. R. Wilson's cloud track apparatus in which by a sudden expansion moist air enclosed in a suitable chamber is put in a condition of supersaturation. The degree of supersaturation is so chosen that in the absence of any nuclei no condensation occurs. Immediately after the expansion a flash of X rays is allowed to pass through the chamber and condensation occurs on the ions that are formed. If suitably illuminated these water drops can be photographed. The X ray beam was limited to a narrow pencil down the centre of the chamber and five separate photoelectrons were visible. Each of the tracks of these photoelectrons shows the history of a separate absorption of a quantum of energy  $h\nu$  by the atom located at the head of the track.

The electrons are ejected with such a high velocity that they can penetrate a considerable distance through the gas. Their path is marked by the ions they form in their passage. In the case of electrons formed by X rays of lower frequency the speed of ejection is less. This is shown in photographs which reveal the greater tortuosity of the paths and the greater density of the water drops along a track.

**The Compound Photoelectric Effect**—This is differentiated from the ordinary photoelectric effect of X rays by the fact that the absorption of the radiation by an atom leads to the ejection of two electrons and not one as in the other case. Its existence although previously suspected was first clearly demonstrated by P. Auger using the Wilson cloud track chamber method. The gas in the chamber through which the X rays passed consisted of a small percentage of a heavy gas such as argon mixed with hydrogen. The argon is found to be responsible for almost the entire X ray absorption and the small stopping power of hydrogen allowed the ejected electrons to traverse reasonably large distances and give good tracks.

It might be thought that the double tracks of the photograph only show a normal photoelectric effect by two atoms so close together that the tracks appear to start from the same point but these double tracks occur far more frequently than would be expected on a probability basis and it is simplest to consider them to come from one atom by some slight modification of the usual process. It will be seen that the further facts support this hypothesis. If a series of such photographs are taken under exactly the same conditions with the one exception that the voltage on the X rays (i.e. the frequency of the X rays) is increased it is then found that while one member of a pair of tracks increases in length as predicted by Einstein's equation the other shows no

change. This must not be taken to show an exception to Einstein's equation but rather that this second track is due to some process in the atom admittedly excited by the primary radiation but yet not directly depending on its frequency. The first action of the radiation is to eject an electron from the atom in the normal photoelectric way and the second track occurs because the atom is left in what is called an excited state that is capable of further changes.

In the article ATOM it is explained how for numerous purposes we can picture the electron in the atom arranged in a series of shells or groups each characterized by a definite energy. The process of radiation is held to be due to the removal of an electron from an inner group and the subsequent filling up of the gap by one of the electrons previously in an outer group. Now in the compound photoelectric effect the primary effect of the X rays is to remove an electron from one of the groups of an argon atom and in the majority of cases this will be from the innermost or K group. The argon atom is now said to be excited in the K group and a subsequent transition of one of the outer electrons into this vacant place will lead to the emission of one quantum of the argon K radiation. Sometimes this radiation escapes from the atom but it may be internally absorbed and never escape at all. In this case the argon atom will emit a second photoelectron whose energy and therefore length of track in the gas is determined by the frequency of the argon K radiation and not by that of the incident X radiation. It will therefore not change when the frequency of the incident X rays is changed. It is possible to secure a second and even a third repetition of this interesting process thereby giving rise to the emission of three or four photoelectrons from one atom.

This phenomenon has been described as if an excited atom always emitted its surplus energy first in the form of radiation but that on occasion this could be subsequently reabsorbed in the same atom. It is held by many authorities that it is rather artificial to imagine radiation to be emitted apparently to exist independently of the atom and then to be reabsorbed all inside the minute volume of the atom. It is maintained that it is simpler to state at once that an excited atom that is an atom with greater energy than the normal has at its disposal two distinct methods of getting rid of its extra energy either by emitting a quantum of radiation or by emitting an electron. There is no doubt that this is a difficult point but a somewhat similar phenomenon occurs among the radioactive bodies when in the opinion of the writer the evidence is strongly in favour of a true internal absorption of radiation.

The phenomenon of radioactivity is due to a disintegration of the central positively charged nucleus around which are the electrons forming the rest of the atom. Frequently accompanying the actual disintegration which involves the emission of a material particle from the nucleus either the  $\alpha$  or  $\beta$  particle there is also an emission from the nucleus of very high frequency radiation called the  $\gamma$  rays. These are of the same type as X rays but of higher frequency. These  $\gamma$  rays are quite frequently absorbed in the parent atom in their passage out from the nucleus through the electronic system and give rise to high speed photoelectrons. As some radioactive bodies emit a considerable number of different frequencies each of which can be converted in either the K, L, M, N etc. levels it will be seen that a great number of photoelectric groups are possible. These may be investigated by the magnetic spectrum method previously described in the case of X rays and illustrated by fig. In this case however since the radioactive body is at one and the same time both the source of radiation and of the photoelectrons it is merely necessary to place a wire coated with the radioactive material underneath the slit to obtain results.

The radioactive body used was Radium B and the radiations have an average frequency corresponding to about 300 000 volts. The great complexity of the spectrum may be seen from this reproduction which only shows a part of the spectrum to obtain all of it different magnetic fields would have to be used. The sharpness and narrowness of the lines is noteworthy. The reason for this is that in this  $\gamma$  ray case all the photoelectrons are due

of the electric vector from rather a different aspect. The experiment was usually carried out with reflecting surfaces of the like metal and an increasing dependence of the number of photoelectrons on the angle of polarization of the light was observed. If the light was incident obliquely and was unpolarized then the electric vector had a component perpendicular to the surface the number of electrons ejected was found to be greater

FIG 3—PHOTOELECTRIC CELL

than if the electric vector lay wholly in the surface. This phenomenon was investigated in great detail by Pohl and Pringsheim who found the variation of the emission with change of wave length of the light when compared on the basis of equal amounts of incident energy. When the electric vector had a component perpendicular to the surface they found a maximum occurred at a certain wave length which was not present with the other type of polarization. This led them to effect a division of the whole effect into a normal and a selective effect the latter showing the maximum.

The important bearing of this subject on the nature of light depends entirely on the surprising fact expressed by Einstein's equation that the velocity of the ejected electron is determined only by the frequency of the radiation and is independent of the intensity of the radiation. This is entirely contrary to what we should expect from a wave motion yet the phenomena of interference and in fact the whole of ordinary optics appear to show undubitably that radiation is a wave motion. This will be apparent if we imagine first a metal plate placed so close to an X-ray tube that the radiation is pouring on to it and then removed so far away that the radiation is even difficult to detect. On the wave picture one would say that in the second case the electric vector in the radiation hitting the plate was very much weaker than in the first and we would expect that not only would the number of electrons be less but also that the electric vector would be able to transfer much less energy to the electrons and they would come out with much lower energies.

Whilst the number of electrons is certainly less in strict proportionality to the intensity the energy of the individual electrons will be the same in both cases. Weak or intense radiation as long as the frequency remains constant always gives the same energy to the electrons. This result is quite incompatible with our ordinary ideas of a wave motion and the simplest way of expressing this is to notice how the alternative picture of light quanta explains the dilemma. If instead of imagining the radiation to spread out from the source in waves we imagine the energy to be emitted in bundles or quanta of magnitude  $h\nu$  then with intense radiation there will admittedly be more quanta traversing a body but even with weak radiation the few quanta which do arrive are still the same. They will naturally lead to the ejection of fewer electrons but when a quantum is absorbed it always involves the transference of the same amount of energy and the photoelectron will have the same energy as if the density of quanta were far greater. Great difficulties are raised by any attempt to explain interference by a light quantum picture and the problem of reconciling these two different views has at present not been solved. A fuller discussion will be found in the articles QUANTUM THEORY and ATOM where it is pointed out that probably both views are correct. The point is that if we insist on

describing atomic processes in language and concepts used for large scale phenomena then inevitably a duality will appear. Radiation must sometimes be pictured as waves sometimes as particles. How far reaching this duality may be seen in the fact that electrons and other material particles also behave sometimes in a manner only explicable on a wave basis.

**Photoelectric Cells**—The practical application of photoelectricity to measuring light intensities is made by means of the photoelectric cell. In its simplest form this consists of a glass bulb silvered internally and on this inner coating is deposited a very thin layer of some metal such as potassium. In the centre of the bulb is arranged a collecting electrode supported on a wire sealed directly through the glass and metallic connection is made to the potassium in the same way. A diagram of such a cell is shown in fig 3. The cell is sometimes suitably mounted in a light tight wooden box. The silver is removed from a certain area of the glass so as to allow light to enter into the cell. The collecting electrode is seen at the bottom of fig 3.

The whole apparatus can truly be described as a photoelectric cell since when light enters the bulb electrons will be ejected from the potassium which will charge up positively and will be collected by the central electrode rendering the latter negative. To measure light intensities precautions must be taken to collect the whole of the electron stream liberated since it is the number of electrons which is directly proportional to the intensity of the light. The method of doing this is to apply a negative potential to the potassium surface as shown in fig 4 the collecting electrode being practically at the potential of the other end of the battery by connection through the measuring instrument. For considerable intensities of light this may be a sensitive galvanometer but in most cases some type of electrometer such as an ordinary quadrant electrometer or the special quick period quadrant designed by Prof. Lindemann is preferable. The most sensitive arrangement is to measure the rate at which the electrometer charges up i.e. the rate at which the needle moves but when it is possible the constant deflection method is far more convenient. It will be noted that while one terminal of the electrometer is connected directly to the collecting electrode the other is connected to earth and the constant deflection method consists in connecting a very high resistance of the order of 10 to 10,000 megohms across the electrometer. The latter then measures the potential drop across this resistance due to the current through the photoelectric cell. An important precaution is to have a guard ring (see fig 3) consisting of a ring of metal or silvering in the position shown and to connect this to earth. This prevents charge creeping over the surface of the glass from the high potential electrode to the measuring instrument. The general working of the cell is rendered far more regular by taking precautions

FIG 4—METHOD OF USING A PHOTOELECTRIC CELL

to keep it in a dry atmosphere as a film of moisture on the surface of the glass renders it virtually a conductor.

While a photoelectric cell constructed in this way gives a qualitative measure of the light entering it it is certainly somewhat insensitive and great improvements have been effected by attention to two points. The first is the correct preparation of the light sensitive surface—potassium in the case already described. It appears that the sensitivity can be greatly improved by the following process. The potassium is carefully purified by distillation and is finally deposited by the same process inside the

## THE MAKING OF BLOCKS

In making any type of block if the reproduction of an original drawing is to be successful attention must be given to every stage of the work the character of the drawing should be considered in relation to the special method by which it is to be reproduced. Originals in line where light and shade are obtained by varying thicknesses of the line are reproduced by a line block. For this purpose the drawing is made in pen and ink each line of which must be solid and opaque i.e. the effect must not be obtained by grey lines or washes but each line must be solidly drawn in black ink.

Photographs wash drawings and paintings are reproduced by half tone i.e. the tones of the original are reproduced by reticulating the subject by means of a screen which may be either grain or cross lined. When photographs especially of a technical character are to be reproduced it is essential that "retouching" of the original be resorted to this is of a highly specialized character necessitating the emphasizing of the parts which are to be specially brought out throwing back the details which are not of such importance and not infrequently eliminating the surroundings. This is done by artists who use pencil ink and frequently aerograph spraying in the preparation of an original for reproduction by photo engraving.

**The Camera**—A specially constructed camera is used its main features being its rigidity and long bellows to allow for enlargement or reduction. The front frame of the camera is firmly secured whilst the back frame containing the focussing ground glass moves in slots which keep it parallel with the front. The camera is supported on a frame on one end of which an upright board is fixed. On this is placed the original to be reproduced it works in grooves so that it can be moved sideways to obtain the correct position. On the front frame of the camera is a section to which the lens is attached this slides up and down to allow for centring of the copy. It is necessary that the copy board and the camera move in perfect unison during exposure and precautions have to be taken to obviate movements in opposite directions through vibration.

Special lenses too are required and those known as anastigmatic are found best for photo engraving. On the lens is a slot into which stops or diaphragms of peculiar shapes are inserted and which act in the same way as the iris or circular apertures used in ordinary photography. The stops used by photo engravers have an important function to perform since they determine the shape of the dots and influence the final results.

For all methods of direct printing the negative has to be reversed i.e. left to right. This is done by passing the rays of light through a glass prism or mirror so that the image is first reflected on to the prism and from thence through the lens. Another method frequently used in America is to make the negative without the use of a prism and after developing strip the film and obtain a reverse. This method is not possible however when making negatives for colour printing. The reversing is necessary to allow for a positive impression of the design to be printed upon the paper.

**Illumination**—In photo engraving great attention has to be given to lighting to ensure that the copy is evenly and sufficiently illuminated. Whilst daylight is most effective it is not always possible to use it therefore artificial lighting has to be resorted to the usual procedure is to suspend two arc lamps from supports one on each side of the copy board these being adjustable to meet the special requirements of the work to be reproduced.

**Photographic Plates**—Either wet (collodion) or dry (emulsion) plates are used in certain classes of work the wet plate being preferred by some photo engravers.

## LINE BLOCKS

When a negative of a line drawing which has to be made into a printing block has been obtained a photographic print from it is placed on to a piece of metal usually zinc which is first thoroughly cleaned by polishing with water and powdered pumice, a felt pad being used for the purpose. The plate is then coated with a solution sensitive to light made up of water

albumen ammonium bichromate and liquid ammonia. The solution is carefully poured over the zinc plate and placed in a whirler which spreads the solution evenly over the surface. This is dried by heat. The negative is then placed film side to the coated zinc plate and put into a printing frame with a plate glass front a close contact being essential. This is obtained by means of screws or by using a vacuum frame. The negative and coated plate (which are firmly secured in the frame) are then exposed to light (usually electric) the time of exposure varying from two or three minutes to ten minutes according to the quality of the negative and the intensity of the light. The negative and plate are then removed from the frame and the metal plate after being slightly warmed is placed on a flat surface and rolled over with a special ink until it is evenly covered. It is then placed in a tray of clean water and the surface gently rubbed over with cotton wool. The albumen coating where it has not been hardened by the action of light is washed away leaving those parts which have become hard and insoluble by exposure to light adhering to the plate. When the clean parts of the zinc are thoroughly cleared the plate is dried by heat and any defective line retouched after which the plate is dusted over with a fine powdered resin which sticks to the ink providing a great resistance to the acid with which the plate is to be etched. It is then dusted with a soft hair brush to remove the surplus resin and subjected to heat which melts the resin or as it is commonly called dragon's blood. When the plate is cool it is ready for etching i.e. it is placed in a bath made up of two oz. of nitric acid and 60 oz. of water for the first etch but before doing so the margins and back of the plate have to be coated with a varnish which prevents the acid etching away those parts to be left unetched. Whilst the etching is taking place the mordant is kept in motion. When this is done by hand the baths are rocked so that the solution flows to and fro over the face of the plate which is brushed during the process to keep the metal clear of oxide machines however are now generally used for this purpose and the acid is sprayed by means of air on to the surface of the plate. When the plate has been a short time in the bath it is removed washed and cleaned dried by heat and another dusting of resin applied in four directions so that each of the four sides of the lines will be protected from the acid which is apt to underbite the lines. The plate is again heated causing the resin in the ink to melt and run down the sides of the etched lines and the operation has to be repeated several times before the necessary depth is obtained.

A more recent practice in the United States saves much time by flowing the zinc plate with a so called enamel solution which eliminates rolling up with ink. The plate is developed in alcohol instead and is then ready for etching.

The line process is occasionally used for colour work. The colours are generally made up of a number of solid tints or stipple the usual method being to take setoffs from the etched key plate and place them on to another piece of zinc stopping out or painting those parts required for the particular colour in which it has to be printed. Where stipple is to be introduced shading mediums are usually employed. These consist of a sheet of gelatine with the design of the particular grain dot line or stipple standing in relief. This is rolled over with transfer ink and placed face downwards on the plate which has been gummed over on those parts where the work is not required pressure being applied by a roller or squeegee to those parts of the setoff from the key plate which have to be printed in the particular ink. Each colour requires a separate plate which is then rolled up powdered and etched in the usual way.

**Half tone Blocks**—The half tone engraving is the process by which full tone subjects in monochrome and colour are reproduced. The negative is made in the usual way but to provide the necessary reticulated surface the exposure is made through a screen. This may be composed of regular grains (mezzograph) or what is most general a series of lines running across each other at right angles. The cross line screen consists of two sheets of thin plate glass ruled with diagonal lines of mechanical exactitude. These are engraved into the glass each piece of glass being ruled at right angles to the other. The lines are filled with

Hitherto the screens are in various gratings or meshes. These vary from 50 to 100 lines to the inch, though for high resolution work 150 to 200 lines are used. The distance between the openings in the grid and the work to be reproduced and the distance between the grid and the photographic plate must also be printed. When printing on chrome or copper a new, gold-colored surface must be made with fine screens require to be printed on a light colored or coated paper. For ordinary black and white commercial work screens from 100 to 150 are used and for fine colour reproductions screens from 150 to 200. The screen is secured in a holder and placed immediately in front of the work slide holding the photographic plate. The screen distance—an important factor—can be adjusted to suit the particular work in hand. When the exposure is made and the negative developed it will be found upon examination that the tones in the original are represented by a large number of dots varying in size according to the tones contained in the original.

The next operation is to place photographically a print from the negative on to a metal plate which for half tone work is usually copper. The solution for coating plates for half tones is different from that used for line work. It is composed of fish glue ammonium bichromate and liquid ammonia albumen occasionally being added. The copper plate has to be prepared by removing all grease and foreign matter. It is usual to heat the plate and rub it back and front with caustic potash finishing off by polishing it with charcoal. The sensitive solution is then poured on the plate and placed in a whirler to distribute the coating evenly. The fishglue solution or as it is usually termed enamel forms an acid resist. After printing down the copper plate is placed in water coloured with an aniline dye the enamel absorbing the dye. The plate is washed in water after which the design becomes visible. It is then dried and subjected to heat or as it is called burnt in the effect being to increase the resistance of the enamel to the etching fluid. The margins and back of the plate have to be painted with asphalt or shellac varnish to protect those parts from the acid whilst etching. The plate is then ready to be placed in the etching bath which is made up of a solution of iron perchloride at a strength of about 40 Beaume. The plate is left in the solution for a few minutes and then examined to see if the etching is proceeding evenly over the whole surface.

The etching of the plate is continued until the fine dots in the higher lights are as small as it is possible to etch them great care being taken that the acid does not underbite the dots. When the etching of certain parts has reached the stage when it would be dangerous to proceed further they are staged or stopped out with asphalt and varnish and the plate again immersed in the bath. A series of fine etching has then to be undertaken *ie* stopping out with an acid resisting varnish those parts which have been etched to their fullest extent and applying a series of local etchings for the purpose of putting life into the plate. This is done by saturating a fine brush with the etch and placing it on the area requiring such treatment. A proof is then pulled from the plate compared with the original copy and any necessary alterations made. When passed the plate is finished and mounted on wood ready for the printer.

When a vignetted block is required the design and close surroundings are protected with varnish and the extreme edges are treated with acid so that the dots on the latter are reduced to the smallest point gradually increasing in size towards the design. In this way graduated results are obtained until the dots merge into the white paper without showing a sharp edge.

When pencil drawings are to be reproduced it is usual to make a high light negative *i.e.* the high lights in the drawing and the paper on which it is made do not show screen. This is done in the making of the negative one of several methods being

1. To correct the direct when an over exposed negative is used during the exposure which tends to make the shadows in the high highlights overlap and become solid the correct one thing brought back to their correct relation by manipulating the exposure when the Bessari Apparatus which can be attached to the camera is used and causes a slight circular movement of the plate to screen or cut out the highlights and allow them to drop in the subsequent intensification of the negative for a plate of the Waterhouse type used to expose one portion of the exposure to transpose the positions of the highlights and the shadows between them thus veiling the shadows which disappear when intensified and (d) the indirect method retaining the use of three photographic plates first a continuous tone negative is made of the original which can be retouched from this a positive is made through a screen and from the positive a negative is obtained with the shadows eliminated from the high + light which include the paper on which the drawing has been made

Combined line and half tone blocks are frequently made for commercial purposes. This can be done either by making two blocks one in line and the other in half tone cutting out the spaces in the line block and inserting half tone plates which must be made to fit the space or by making two negatives one in line and the other in half tone stripping the films from the photographic plate and placing them in their respective positions on a piece of glass which constitutes the negative used for printing down on to metal. In this way the combined design is etched on one plate and at one operation.

**Colour Work**—When reproducing colour subjects by the half tone process the blocks are made in the same way as half tones but the photographic plates must be colour sensitive (panchromatic) and when making the exposure the light not only passes through the prism lens and screen but also goes through what are known as colour filters. These are optically flat coloured pieces of glass held in a frame attached to the lens and as the light passes through the particular filter only certain rays of light reach the photographic plate. A special colour filter is used for each colour negative. Thus a negative only records the colour and its component tints of one of the fundamental colours of the spectrum.

To make a negative for the yellow printing plate a blue filter is used for the red printing plate a green filter and for the blue printing plate a red filter. The light passing through the respective filters prevents the colours and tints not complementary to the inks in which the printing blocks are printed being recorded on the special photographic plate.

As in the production of the half tone plate the ruled screen is placed in front of the photographic plate but for colour work a circular screen which can be set to different angles is used for each of the colour negatives. The angles of the screen must be different for each colour to prevent a pattern or moiré effect taking place when the three colours are superimposed in printing. One of the colours has the screen angle at 45° from the vertical and the others 75° and 15° respectively. The negatives are developed, printed down on to metal and etched in the same way as when making a monochrome half tone plate but much fine etching demanding great skill has to be done in the production of colour subjects. The fine etcher must possess a good knowledge of colour and its analysis so that the final results approximate to the original painting. He has to endeavour to rectify the shortcomings of the means taken to dissect the colours of the original and the inability to obtain photographically a true rendering of the colour values on the negative. Thus he does by a series of fine etchings stopping out certain parts and continuing the etching by local application. This operation may have to be repeated a number of times and many proofs from the plates pulled before the desired results are obtained.

It is now usual to include a fourth colour when reproducing coloured subjects. This is usually printed in a grey or black the colour however is not dissected in the ordinary sense of the term although an amber filter is used. The fourth plate represents the whole of the tones in the original in their proper relation

The first in the production of a glossy paper which reflects the light and hence this will provide letterpress printers with a means of producing half-tone work with rotogravure and offset printers in producing half-tone work on uncoated paper in place of the highly finished paper which must be used if the best results are to be obtained from a half-tone block.

Hackleman *Commercial Engraving and Printing* (Indianapolis 1921) deals with all aspects of photo engraving and its allied branches. S. H. Horgan *The Figuring Primer* (1911) contains concise working instructions in line and half-tone engraving. E. S. Pilsworth *Process Engraving* (1921) gives formulae etc. H. A. Groesbeck *Process & Practice of Photo Engraving* (1914). L. P. Clerc *Ilford Manual of Process Work* (1916).

The half-tone process is applied to the preparation of printing surfaces for various methods of reproduction including plates and cylinders for machine printed photogravure and photo lithography. The preparation of the negative for the latter is similar to that followed when making half-tone blocks with the exception that a red wax which is to be used for printing by offset is not required. This is achieved by removing the prism from the lens. Extreme care has to be taken when making a negative for art photo lithographic printing to see that the full range of tone are contained in the negative. It is not possible in these processes to retouch the plates in the same way as the photo engraver does when making relief printing blocks. The chief advantage of the c method of printing is that a rough surface paper may be used and attempts are being made to produce relief printing blocks which will answer the same purpose.

The printing of these special plates may be briefly described as follows. A filler of chromium is electrolytically deposited on a sheet of copper. The chromium coated plate is floated with a solution of albumen sensitized with ammonium bichromate. A high light negative (the form of negative usually employed) is placed in contact with the sensitized plate in a pneumatic printing frame and exposed to light. After rolling up with litho ink the plate is developed by washing in water and then dusted with finely ground bitumen. The ink and the bitumen combining during the subsequent process of burning in to form an acid resist. The plate is then placed in a dissolving bath the mordant being hydrochloric acid and glycerine kept at a temperature of 75° F. The action of the bath removes the chromium coating from between the dots or lines representing the design, and is continued until the bare copper plate appears when it is transferred to a saturated solution of potassium cyanide. After a further washing in water it is placed in a bath wherein silver is electrolytically deposited on the copper portions between the dots. A sponge saturated with benzol is then used to apply a powder composed of mercury and chalk to the plate this latter amalgamating with the silver produces ink rejecting areas whilst the benzol removes the bitumen resist.

The printing plate therefore consists of a chromium covered surface which accepts the ink whilst the spaces between the dots or lines comprising the amalgam of silver and mercury repel the ink as the inking rollers pass over the plate. The ink and rollers used for this process contain a small percentage of mercury. It is claimed that Pantone makes possible the printing of half-tone illustrations on any grade or finish of paper the plates themselves being practically indestructible.

Another method of producing colour work from relief printing blocks to print on a rough surface paper is known as the 'Blackmore Tintex Process'. The plates for this process are 'deep etched' in a special way.

It is probably along these lines that half-tone blocks for ty-

will be developed. Since most people have a misconception of a glossy paper which reflects the light and hence this will provide letterpress printers with a means of producing half-tone work with rotogravure and offset printers in producing half-tone work on uncoated paper in place of the highly finished paper which must be used if the best results are to be obtained from a half-tone block.

**PHOTOGRAPHIC ART** The modern tendency in photography in the hands of both amateur and professional exponents is to employ the camera as a means of artistic expression. No consideration is being taken here of the widespread applications of photography in scientific and technical directions (See **PHOTOGRAPHY**). It is more in reference to its position in the realms of art that this article is written. The appeal to the eye is greater than the appeal to the emotions through any other sense and in this respect photography occupies a unique position today as a maker of pictures. Many thousands of individuals in all parts of the world are producing photographs with the ulterior object of their appeal to the eye as pictorial representations of incidents of interest. Unfortunately a very large majority of those who use the camera are not artists in this way the prestige of photography as an art is apt to suffer.

Photography can be regarded as an art in precisely the same way that any other graphic process can be regarded as an art when it is dealt with and conducted by an artist. The process is really a medium of expression and the camera lens and sensitive material merely the tools employed. The true artist who seeks to express himself can within the limitations of his tools and material do so in any medium that appeals to him for the purpose and the measure of success that attends the result of a work of art is entirely the measure of the ability and inspiration of the artist. It is recognised that photography has limitations that are imposed by the apparatus employed. When these are recognised the camera becomes a most facile instrument as a means of expression and the main idea of picture making in photography is precisely the same as that which is put forward by the artist with any other medium. It is in brief that the individual with some thing to say is never inarticulate. He may find paint or music or the pen most responsive for his expression. Photography with its remarkable ease of production has solved the difficulty for many.

In 1840-1853 Daguerreotype and Calotype were very popular and a Scottish artist D. O. Hill made a series of portraits in Calotype in 1844-1845 which are still regarded as remarkable examples of pictorial portraiture (See **PHOTOGRAPHY History**). From that time onwards a great variety of investigations and experiments were conducted in photography and the work steadily progressed towards the simplification of methods. An outstanding development was the introduction of the gelatine process dry plates were regularly used and the foundations of modern photography were laid. From this time onward the progress in both commercial and amateur photography became very rapid as both the materials and the apparatus were being steadily improved year by year. Printing processes increased and cameras were simplified.

**Colour Photography in Art.**—The photography of coloured objects received attention in the early stages of the history of photography when it was observed that the tones rendered in

[illegible]

Processes in which coloured resins have been applied have also been arrived at in cinematography as well as in printing processes in which the colours have been entirely under the control of the producer of the print and can hardly be regarded as colour photography at all.

**Printing Processes**—In recent times printing processes have also been perfected and others have appeared in which personal control has played great power in the hands of the worker for pictorial effects. In regard to the direct printing process one of the earliest silver methods in which the silver salts were incorporated with albumen is no longer employed. Gelatine has taken the place of albumen and printing out papers have been of the variety known as gelatine chloride. In these chloride of silver and gelatine have formed the base of the emulsion coating the paper the image has been printed out beneath the negative and subsequently toned. Still more recently bromide and gaslight paper have been the most popular printing media the former being paper coated with an emulsion of bromide of silver and the latter with chloro bromide of silver. Both of these are known as development papers the image being latent after the exposure and has to be chemically developed to produce a visible image. Many varieties of chloro bromide papers are in use to day and are proving extremely popular printing media for pictorial workers both amateur and professional.

On the control processes gum bichromate was popular for a period and is still used by some pictorial workers. In this process paper is coated with bichromatised gum and a suitable pigment. After exposure under a negative the parts that have not been acted on by light and rendered insoluble are washed away in water. The personal control in the result is entirely in the hands of the worker according to the desired result. To a certain extent this process is similar to the carbon process in which pigment and bichromatised gelatine are coated on paper and after exposure beneath a negative the tissue is placed in contact with another support and the image developed in hot water by dissolving away the unacted upon gelatine.

The most recent developments in control processes have been in oil and bromoil the former being founded on the action of light on bichromatised gelatine which is coated on to plain paper exposed under a negative and then soaked in water. The parts that have not been acted on by light absorb water in proportion to the light action. In this condition those parts of the print which have been acted upon by light and represent the shadows of the original subject can be made receptive to an oily pigment when dabbed on with a suitable brush and the picture thus built up in pigment. The original drawing of the photograph is retained but the tone values are entirely under the control of the operator. In the bromoil process a print on bromide paper is bleached in a solution in which bichromate salt appears the bleached image taking on the same qualities when soaked in water as the printed bichromate image in the oil process and pigment is applied in the same way.

The carbro process is a development of the carbon process in which the same principle applies and both carbro and bromoil processes have become very popular among pictorial workers in photography not only on account of the control in the final result that is placed in their hands, but from the fact that the prints can be made from enlargements on bromide paper made from small negatives.

In amateur work in particular small negatives with subsequent

clearing of bromide paper produce finished results either in that race or in bromoil that account for a large proportion of our interest in it. All the tendency to day towards simplification in making the camera more effective the apparatus for the professional worker. The portable hard camera with speeded shutter, large aperture lens and high speed plate and films have rendered the production of negative of high quality possible to the amateur while in the hands of the expert the possibilities are available for use.

**Controlled Processes**—The real factors that decide the use of a picture by photography are those which occur before the exposure is made and after the negative has been developed. The use of accurate apparatus intelligently used with a knowledge of its limitations and with the employment of the right type of plate or film is a matter within the scope of practically anyone. For the production of pictorial work which may rank as art the mental outlook that precedes the taking of the photograph and the manipulative processes that occur in the making of the final print will determine the artistic quality of the result. The selection of subject, choice of viewpoint and due consideration of the lighting direct has three elements of picture making where the trained artist has the advantage and it is in these respects that the photographer who is an artist can make the most of his subject, using the apparatus thereafter merely as a recording instrument to secure in a fraction of time the picture that has been visualized. The photographer therefore who is by instinct an artist or who has had an art training is more likely to make photographs that can rank as art than the snapshotter without the qualifications. After the plate has been exposed and the negative developed it is in the production of the final print that the artist again finds scope for individuality. The same negative mechanically printed on the one hand or treated with care and thought by an artist to produce a beautiful picture by a controlled process on the other hand can be two widely different things. It does not necessarily mean from this that controlled printing processes employed indiscriminately and without very definite knowledge of the final result required will produce a picture where there is much evidence to the contrary. But many of the finest pictorial results by photography that rank high in pictorial art have been produced by one of the various controlled processes when employed by a worker who is an artist.

**Bromoil Process.**—Of these processes probably the one most widely employed at the present time is the bromoil process. Bromoil has much in its favour for every worker who desires to express individual feeling and control in a pictorial photograph and has the great advantage that unlike many other photographic processes in which considerable control is possible a finished print on a large scale can be made with perfect facility from a small negative taken with a pocket camera. The artist therefore who is equipped with a small but reliable camera and a knowledge of the picture he requires can produce with its aid exhibition pictures of large dimensions impractical before the introduction of the bromoil process.

In the bromoil process the original negative which should be of good quality with the correct range of tonal values is enlarged to the desired size by one of the ordinary methods of enlarging on to ordinary bromide paper. This enlarged bromide print then forms the basis of the bromoil print. The print after developing, fixing and washing is treated with a special bleaching solution which has the quality of converting the black and white silver image in the gelatine of the bromide print into a bleached image with at the same time a tanning action on the gelatine. This tanning action is in direct ratio with the tones of the original image. Thus the darkest part, or shadows of the picture become the parts that receive the greatest tanning action, the half tones less in proportion to their strength, and the high-lights very little or not at all. The subsequent pigmentation of the image with a greasy ink is regulated by the absorption of water in the gelatine. Where the image has been tanned or hardened by the action of the bleacher there is not much absorption of water, whereas in the high lights where the tanning action has not occurred, a considerable amount of water is absorbed, and those parts in turn

the high light areas of the original print are then touched with the brush. The brush is then dabbed on the surface of the prepared print where it will be found that the pigment will adhere to those parts which formed the original image with the high lights reject the ink. From now on the process is a matter of application of the pigment to the surface of the print building up the image tone by tone until the complete picture is made visible in pigment. A certain amount of practice is required and desirable before the correct colour for giving the pigment is acquired but when it has been acquired the printing of a comparatively large print becomes a simple matter that is entirely under the control of the worker who is then able to reconstruct the subject with stronger tones where required or high lights filled in where necessary. A slow pre-inking on of the brush will tend to add more colour while a quick hopping action will remove it. The colour should always be applied thick and by continuing to work on the surface the texture will become finer until the right depth of tone is reached. Stronger shadows are produced by using a harder ink which will tend to produce contrast whilst softer inks should be used to tone down high lights and to make a more even tone over the entire picture. The pigmented print should be allowed to dry naturally in a warm atmosphere and the surface should not be touched until the pigment is hard when final spotting and cleaning up can be undertaken.

The following is a good formula for the bleaching solution —  
 Copper sulphate 1 oz  
 Potassium bromide 1 oz  
 Potassium bichromate 60 grain  
 Hydrochloric acid 6 minimum  
 Water 6

For use one part of this solution should be diluted with three parts of water. To bleach the print it should first be placed in water for a minute until limp and the surface evenly wetted the water poured off and the bleaching solution poured evenly over the print. In from three to four minutes the black and white image is converted into a faint brownish image. When fully bleached the print should be thoroughly washed for a quarter of an hour and then fixed for ten minutes in a plain hypo bath containing 1 oz of hypo to 20 oz of water. This is followed by a final washing of a quarter of an hour. The bleached fixed and washed print should then be dried and although it is possible to proceed with the pigmentation immediately after washing better results are obtainable by first drying.

To prepare the bleached print for pigmentation it should be soaked in water at a temperature of 65° Fahr for about half an hour. This will permit the gelatine to absorb water in inverse proportion to the shadows of the original image. The print after soaking is placed on a pigmentation pad consisting of several thicknesses of wet blotting paper laid evenly on a hard surface such as a sheet of glass. The wet pigmentation pad is necessary to keep the print in the correct moist condition during the application of the greasy ink.

The wet bleached print is now carefully blotted with fluffless blotting paper until surface dry and the image will be observed in the gelatine in very slight relief. The high lights which have absorbed most water have a distinct shine while the shadows are matt in appearance. The pigments employed are specially prepared for the purpose and are similar in character to ordinary artists' oil colours but are much stiffer. They are obtainable in practically any colour and in different degrees of hardness but a very hard or stiff ink can be softened by using the medium sold for the purpose or megilp. The brushes are also specially made for the process and are approximately in the shape of a horse's hoof with a slightly domed surface and are usually made of fitch (pole cat hair). It is possible to use brushes made of other hair and even of hog hair but these are generally too coarse for fine work. One or two large brushes and some small ones are necessary for different parts of the work. To apply the pigment a little of the colour should be taken from the tube and spread on a piece of glass or similar hard surfaced palette. A medium sized brush which should be held lightly in an almost vertical position is dabbed on the pigment and the dabbing continued on the palette

until an even film of colour has been spread. The brush is then dabbed on the surface of the prepared print where it will be found that the pigment will adhere to those parts which formed the original image with the high lights reject the ink. From now on the process is a matter of application of the pigment to the surface of the print building up the image tone by tone until the complete picture is made visible in pigment. A certain amount of practice is required and desirable before the correct colour for giving the pigment is acquired but when it has been acquired the printing of a comparatively large print becomes a simple matter that is entirely under the control of the worker who is then able to reconstruct the subject with stronger tones where required or high lights filled in where necessary. A slow pre-inking on of the brush will tend to add more colour while a quick hopping action will remove it. The colour should always be applied thick and by continuing to work on the surface the texture will become finer until the right depth of tone is reached. Stronger shadows are produced by using a harder ink which will tend to produce contrast whilst softer inks should be used to tone down high lights and to make a more even tone over the entire picture. The pigmented print should be allowed to dry naturally in a warm atmosphere and the surface should not be touched until the pigment is hard when final spotting and cleaning up can be undertaken.

**Bromoil Transfer Process**—A further development of the bromoil process producing final prints of great beauty in pigment on plain paper is bromoil transfer. This as its name implies consists of transferring the pigmented image to another base of selected paper. In this case the pigmented print while still wet is placed in contact with the new base and between suitable supports (thin metal plates) is passed through a roller press under considerable pressure similar to an etching press. If the paper is in proper condition the pigmented image is transferred from the bleached bromide print to the new base. If the transferred image is not sufficiently strong the original print can be repigmented and a supplementary pull made for strengthening the transfer care being taken to secure correct registration. Pictures produced in the bromoil transfer process are thus in permanent pigment on a permanent base and comparable in the method of production with pictures in other graphic media in which an inked up plate is pulled in a press.

**Process and Expression**—Apart from the progress in processes apparatus and materials the individual side of photography has grown even more rapidly but it must be admitted that as in all other realms of art the individual with strong personal proclivities in regard to the rendering of any particular subject matter is always independent of the process. The peculiar advantages of photography for recording incidents textures and subjects beautiful *per se* should have more than a passing claim on the attention of all who may regard it solely as a means of expressing artistic thought. There is nevertheless a tendency nowadays to confuse the process with the expression. To the artist the latter is the first consideration the photographer who is not an artist is concerned chiefly with the process and it is with this clear division of interest that one has an opportunity of comparing results. To know the man is frequently to know his work but on the other hand the product does not always betray the man. The imitative faculty which the fatal facility of the camera has so readily engendered renders the simulation of an accepted convention a matter of ease for the unoriginal. The same facility has however the saving grace that it enables the beginner with something original to say to express himself nearly as well as the expert with but a few stock phrases.

The great increase in the number of photographers both those who are attracted merely by the ease with which a picture is made or the artists who have pictorial intentions has been productive of vast numbers of photographic pictures yet the original workers in the art who have produced the best pictures at various times remain pre eminent. The multiplication and simplification of photographic processes have done much to smooth the path for the modern worker and if a photographic exhibition of fifty years ago or even a quarter of a century ago could be reconstituted and

the relative would therefore be a factor to be considered. It would be chiefly of number however. There may be a sure sale for a her action. I'm sure that the relative would have no doubt about the sale of the oil with the requirement of the judge or the court. There is one other thing to be considered. The development of the more practical use of power in such a gun, the more oil he would be able to put into a vehicle or the machine and the more the more content to copy outward appearance but in the same time. The camera is likely to become in an increasing use in instrument for the artist.

The progress toward perfection in pictorial photography is undoubtedly one of difficulty for many, but there are those who have nearly attained it. There are three problems to solve for the worker who is an artist and would use the camera to express his art: the technical problem embodying his choice in mastery of the process that is most fitting to individual requirements; the problem of artistic vision involving all the subtleties of tone perception, values, light, atmosphere and selection; and then there is the question of expression in which are comprised such matters as decorative and appropriate compositions, emphasis and simplification. (See PHOTOGRAPHY.) (I. J. Mo.)

**PHOTOGRAPHY**, the science and art of producing pictures by the action of light on chemically prepared (sensitized) materials (Gr *φως*, light and *γραφειν* to write)

The practice of photography depends upon the sensitiveness of silver compounds to light. When silver bromide dispersed in a suitable medium such as gelatine is exposed to light it undergoes a change as a result of which it becomes *developable*. When after exposure it is treated with a solution of a particular type having reducing properties termed a *developer* the exposed bromide is reduced to metallic silver and forms an image corresponding to the intensity of light to which it was exposed. (See fig. 1)

After development the unexposed silver bromide is removed by a suitable solvent which does not attack silver but dissolves the bromide and the picture is then permanent and is said to be fixed. The picture thus obtained is a *negative*, that is, the

The first two are the best in the picture and the  
 third is the best of the silver bromide last are  
 the best.  
 I don't know how to describe in which the light and  
 the color are the best in subject the picture  
 is the best. The picture is the best with another picture.

FIG 1—THE PRODUCTION OF A PHOTOGRAPH

of creative matter which is exposed to light through the negative and this gives in 'turn a positive image. (S. I. & I.)

The operations required to produce a photograph are thus

- 1 Preparation of the sensitive negative material
- 2 Exposure in a camera
- 3 Development with the after processes fixation washing and drying
- 4 Preparation of the sensitive positive material
- 5 Printing
- 6 Development fixation washing and drying of the print

In the early days of photography all of the operations were carried out by the photographer but at the present time the sensitive material both negative and positive are almost always made by manufacturing companies. In many fields of photography only the exposure including of course the selection of the subject is actually carried out by the photographer himself the remaining operations being performed by others.

A wide variety of negative materials, cameras and printing processes are used in photographic operations their selection depending upon the particular branch of photography under consideration.

The chief branches of photography are

*Amateur Photography* including both the casual taking of photographs for record or amusement and the serious pursuit of pictorial photography as an art.

*Professional Photography* which may be subdivided into *Portraiture* and *Commercial Photography*

Motion Picture Photography (qv) both professional and amateur

*Radiography* photography by means of X rays for medical scientific and industrial purposes

*Applied Photography* including many uses of photography in connection with the arts and sciences such as aerial photography photomicrography astronomical photography photographic recording etc

To these must be added *colour photography*

[illegible]

Previously the most usual type of sensitive paper used were prepared with an emulsion containing free soluble silver compound and were printed under the negative in strong light until the image was complete—*printing out papers*. No development was required with these papers which are however almost obsolete now except for the preparation of *proofs* submitted by professional photographer to customers.

Many other varieties of printing processes are known and some are still being used to a limited extent.

## HISTORY

Photography was discovered by no one man. It was the outcome of the early observations of the alchemists and chemists on the action of light, a subject that belongs strictly to the domain of photochemistry (9). Although the blackening of silver salts was known in 1568 it was not until 1727 when J. H. Schulze of Germany used a mixture of silver nitrate and chalk under stenciled letters that it was definitely recognized that this darkening action was due to light and not to heat. These experiments were important in that in conjunction with those of K. W. Scheele (10), they led to the experiments of T. Wedgwood with silver nitrate on paper and leather in 1800 which were reported to the Royal Institution of London with the suggestion that silver chloride was more sensitive. These were practically failures because of the very long exposures required and no means were then known of removing the unaffected material and thus stabilizing the image against light.

**Camera**—Leaving for the time being the question of the sensitive salts we may turn to the evolution of the camera. This was the outcome of the old camera obscura the invention of which is usually ascribed to Baptista Porta 1553 though its principle had been indefinitely described by Alhazen 1100 Roger Bacon 1267, and others Leonardo da Vinci who died in 1519 described and pictured a camera obscura in an unpublished manuscript. In 1550 J. Cardan suggested the use of a speculum or concave mirror in front of the instrument and D. Barbaro 1568 proposed convex lenses and the use of a diaphragm to secure greater sharpness of the images. E. Danti 1573 corrected the reversed image by means of a mirror behind the lens a device still in use. K. Risner who died in 1580 described in his works published in 1606 the methods of enlarging and reducing and a portable box in lieu of the cumbersome fixed hut in use until then. Porta in his second edition 1589 of which an English translation was published in 1658 was the first to introduce the use of the convex lens in the camera. Kepler the famous astronomer in his work on optical astronomy 1604-1611 described the use of a concave lens behind the convex to obtain larger images and thus anticipated the telephoto lenses of the present day. In J. Zahn's book 1665 there was described a portable camera obscura with two or three lenses to secure greater brilliancy of the image, and side wings to shield it from extraneous light thus with the reversing mirror he antedated a type of modern camera. At the beginning of the eighteenth century the portable camera obscura had become a regular article of commerce and was used to obtain sketches from nature.

**The Beginnings of Photography.**—A. Senefelder discovered lithography in 1796 but though it was introduced in Paris in

As it became a success and a fashion, from his date until 1817, J. Nicéphore Niepce was engaged in an examination of the French natural stones to find one suitable for his process. Since he was unable to draw his son into the matter, he worked on his work, and when the latter was called for military service, Niepce was obliged to produce the images automatically. In conjunction with his brother Claude, Niepce first etched photographs with silver chloride on paper. The light action of iron, iron salts, and other compounds was tested, the metal and paper being used as supports. Finally, gum arabic was tried and then asphaltum or bitumen of Judea, which had been in common use as an etching ground since the days of Rembrandt. This being in soluble in its usual solvents by the action of light gave not only a resist for the etching of metal plates but also transparent images on glass. A successful result was obtained in 1816, and thus it may be said that the first permanent photograph was made in that year by Niepce.

The next three years were required to perfect the process of heliography as it was called and in 1806 an etched metal plate was sent to M. Lemaître of Paris to be printed. In order that the pictures should be more distinct they were exposed to the vapors of iodine. The highlights of the plates consisted of hardened bitumen, the shadows of the bare metal, thus the contrasts were very poor which led to the use of tin instead of copper. Lemaître suggested silvering copper plates. These two facts are of importance in the subsequent history.

**Daguerreotype**—In 18 6 Daguerre a painter who had experimented with silver salts heard of Niepce's work and approached the latter as to the formation of a partnership. This was consummated in 18 9. The work which Daguerre had done with Niepce had drawn their attention to the light sensitiveness of silver iodide and Daguerre discovered accidentally that the effect produced by exposing an iodized silver plate in a camera would result in an image if the plate were fumed with mercury vapor. The inventions of Niepce and of Daguerre were published to the world simultaneously by the French Home Minister in a bill presented to the House of Deputies proposing a national reward to the inventors. A full description of their methods was presented on August 19 1839 at a meeting of the Academy of Arts and Sciences.

The introduction of the Daguerreotype process was attended by complete success. The process required much care and skill. A silvered copper plate was buffed and burnished to a high degree of polish. It was then iodized by careful fuming with iodine and later (1840) resensitized with bromine and then given an exposure the duration of which was of vital importance. At first exposures of minutes in bright sunlight were necessary but later exposures were secured in a few seconds under favorable conditions. The development was effected by placing the exposed plate over a cup of mercury heated to about 75° C. The image was then fixed with a solution of thiosulphate of soda and toned by treatment with gold chloride. The results obtained were excellent when all the operations had been carried out correctly and the process flourished especially for portraiture until it was superseded by the wet collodion process in 1851.

**Calotype.**—A preliminary notice of Daguerre's success was made by Arago to the Académie des Sciences in Paris on Jan 7 1839 This caused Fox Talbot an Englishman to write to Arago claiming priority in regard to the obtaining of a picture in the camera and having rendered it permanent Talbot began his experiments in 1834 using the camera obscura with silver chloride and common salt or potassium iodide as fixing agents A communication was made to the Royal Society of London on Jan 30 1839 But not until a month later did he disclose his working method which then involved silver iodide with excess of the nitrate and fixation with sodium thiosulphate The solvent action of this for silver salts had been discovered by Sir J W F Herschel in 1819 Talbot's process was called "Calotype" and the light image was developed with gallic acid the action of which had been discovered independently by the Rev J B Reade but had not been published by him

The developed image on a sheet of Calotype-paper was the

**MACHINERY USED IN THE MANUFACTURE OF FILM**

1 Film coating machine 2 Solutions in drums used in the manufacture of film base

[illegible]

Herschel also tested the use of glass plates and the deposition of silver chloride thereon. In 1845 Nicéphore de Saint-Victor, his nephew, and Nicéphore Niepce suggested albumen as the vehicle for the sensitive silver iodide. This process called the Niepce type held its own until 1851 when Scott Archer and English architect published his wet collodion process which is still in use in photo-mechanical establishments.

**Collodion Process**—Collodion a solution of nitrocellulose in alcohol ether was first prepared by Maynard of Boston for medical purposes. Schonbein the Swiss chemist discovered nitrocellulose in 1846. To a solution of pyroxylin in ether and alcohol Archer added a soluble iodide usually with the addition of a little bromide and coated a clean glass plate with the iodized collodion. In the darkroom the iodized collodion was sensitized by immersion in a bath of silver nitrate and formed silver iodide with excess of silver nitrate. The plate was exposed wet in the camera developed by pouring on a solution of pyrocollon containing acetic acid and fixed with a strong solution of thiosulphate of soda for which cyanide of potassium was later substituted. Archer's collodion process was not patented and in three or four years it displaced both Calotype and Daguerreotype.

The necessity for preparing the plates immediately before exposure and developing them immediately after considerably limited the practice of photography. Spiller and Crookes suggested bathing the prepared plates in a solution of a hygroscopic salt so that they could be kept some time both before and after exposure. This was followed by the use of hygroscopic substances of all kinds.

**Collodion Emulsion**—In 1864 B J Sayce and W B Bolton described the preparation of an emulsion of silver bromide in collodion. With this preparation the nitrates—the by products of the formation of the silver halide from the nitrate and alkaline halide—were left in the emulsion. In 1894 W B Bolton showed that it was possible to wash these nitrates out and his methods are still followed.

Collodion emulsion was a practical advance on wet collodion but involved no improvement in the matter of sensitivity. Fundamental contributions to this were made by the introduction of alkaline development by Major Russell in 1862. A considerable increase of sensitiveness was obtained with collodion emulsion but the full fruit of this was reaped only with the introduction of gelatino silver bromide dry plates.

**Gelatine Emulsion**—In 1871 Dr R L Maddox made an emulsion of silver bromide in essentially the same manner as that used for making collodion emulsions but he replaced collodion by gelatine. The matter was followed up by other experimenters among whom may be mentioned J Burgess and J Kennett. Kennett placed on the market a dry washed emulsion which photographers could dissolve in warm water and use as a coating on glass and thus produce their own plates.

A great amount of experimental work was at once commenced on gelatine emulsions, the records of which filled the photographic journals between 1873 and 1885. The by-product salts were removed by washing. Abney recommended the use of iodide in small quantity with the bromide and found that this made it possible to obtain faster emulsions with less fog. Digestion, or 'ripening' as it was called, came into use—long digestion at low temperatures being suggested by Bennett—in 1878, and digestion with ammonia was used in 1876 by J. Johnson and in 1879 by Monck.

I was informed by [redacted] at Liverpool Dry Dite  
[redacted] that they had no information available  
regarding the matter.

[redacted]

After the first half of their research, the researchers found a significant increase in the number of eggs laid and in the number of eggs that were laid and incubated since the start of the study. The increase in the number of eggs laid was probably due to the increase in the number of eggs that were laid and incubated. The increase in the number of eggs that were laid and incubated was probably due to the increase in the number of eggs that were laid and incubated.

I am interested in a high point to record the advance made in photography in terms of the relative sensitivity of the process.

Process	Date	Time of exposure
Helicobacter	1860	6 hr
Dactyloctenium	1861	30 min
Chlorella	1862	
Wetland	1863	10 c
Chlorophyllin	1864	15
Chlorophyllin	1865	15 sec
Chlorophyll	1866	60

**Colour Sensitivity**—The silver halides are sensitive chiefly to the blue violet and ultra violet rays hence all other colours are reproduced as drab greys or black. In 1853, H. W. Vogel of Berlin discovered that the addition of certain dyes to the emulsion or immersion of the coated plates in a solution of dye increased the sensitiveness to the less refrangible colours.

Following this Waterhouse found that eosin sensitized collodion emulsion and shortly afterwards Clayton and Tailfer found that eosin would sensitize gelatine emulsions. They obtained a patent for its use in England and France and their plates were placed on the market under the name of isochromatic plates. In 1884 eosin was replaced by erythrosine which was found by Eder to be a better sensitizer and since that date erythrosine has been used almost exclusively for the use of the so called isochromatic or orthochromatic materials. In 1901 Mieth and Traube of Berlin found that ethyl red an isocyanine dye gave strong colour sensitiveness as far as the orange of the spectrum and in 1905 Homolka working at the Hoechst Dye Works discovered Pinacyanol a dye of structure somewhat similar

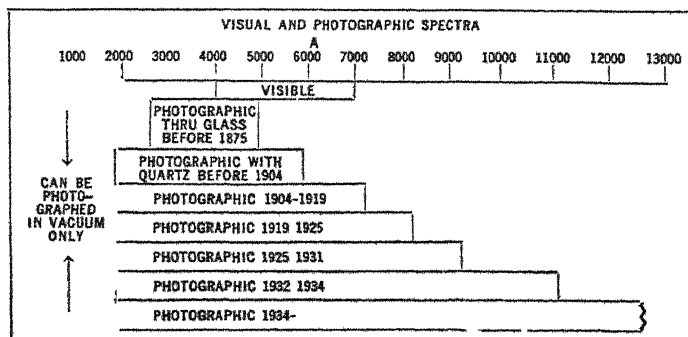

FIG 3 — PROGRESS IN THE COLOUR SENSITIZING OF PHOTOGRAPHIC MATERIAL

to ethyl red but which sensitizes very powerfully throughout the red

It was now possible to make 'panchromatic' plates which would photograph the entire spectrum without difficulty and such plates were placed on the market in 1906

In recent years enormous progress has been made owing to the discovery of new classes of dye which confer extremely high sensitivity through the visible spectrum and far out into the infra red. (See fig 3)

**Film.**—The weight and fragility of the glass support led to attempts to replace it by lighter and flexible substitutes. In 1884, the film roll system of photography was invented by W. H. Walker, the emulsion being coated on paper and a machine for

The first camera used for photography was the camera obscura. It was a box with a lens at one end and a screen at the other. Light from an object outside the box entered through the lens and formed an inverted image on the screen. This principle was used by the camera obscura in the 15th century.

The first camera used for photography was the camera obscura. It was a box with a lens at one end and a screen at the other. Light from an object outside the box entered through the lens and formed an inverted image on the screen. This principle was used by the camera obscura in the 15th century.

In 1891 daylight loading film was made. The film was wound on a wooden core inside a light tight box and black cloth leaders were attached to the ends of the film. Later the film was wound inside a protective sheet of black paper leaving uncut over length to permit loading of the camera without fogging the sensitive film. This was further modified in 1901 when a non curling film was produced by coating the back of the film with plain gelatine.

In 1913 roll film packing was further modified by spooling the film in a thin and translucent red paper the film being protected from light by the use inside this of carbon paper similar to that used for duplicating on a typewriter. After exposures are made the photographer can write on the red paper with a stylus through an opening in the back of the camera. The pressure of the stylus removes some of the opaque black carbon from the sheet so that on exposure to light the film is exposed along the tracks of the writing and the image develops with the negative and serves for its identification.

In 1895 positive film was introduced for the printing of motion pictures the film used previously being of the negative variety only. In 1909 slow burning motion picture film was first made by the substitution of cellulose acetate for cellulose nitrate as the plastic used in the preparation of the base.

Another method of packing films was invented in 1903 and was introduced on the market under the name of film packs. These are now used mostly in cameras of the type originally designed for employment with dry plates.

They have the considerable advantage of not requiring a special roll film back. During recent years flat cut films have taken the place of plates to a considerable extent especially in professional photography.

In 1917 X ray films coated on both sides with emulsion were introduced. Owing to the transparency of the material to the X rays this enables double the density to be obtained and the use of this film is now general throughout the world it having almost entirely replaced plates in radiographic work.

In 1923 motion picture film 16 mm wide on cellulose acetate base was introduced packed in such a manner that it could be loaded into small motion picture cameras without the use of a darkroom. This film was designed for finishing by a reversal process in which the first negative is removed by a bleaching bath and a positive is then printed on the remaining silver bromide. In 1932 a similar film 8mm wide was introduced. The use of these films has led to a great advance in amateur cinematography.

**Developing Agents.**—In the Calotype process gallic acid was used as the developer for the latent image but in 1851 Regnault of Paris and Justus Liebig simultaneously discovered the more energetically acting pyrogallol which actually allowed shorter ex-

posure times. This was used also at first for wet collodion and later for dry collodion. Pyrogallol was an important ingredient of the collodion. Wadley proved that pyrogallol could be used as a developer. C. Russell and J. Leach independently discovered the development of the former suggestion. Even after the introduction of the collodion process pyrogallol was the only developer used when the alkaline carbonates became available. In 1854 Arnold Spiller recommended the use of hydroquinone. In 1854 M. Andresen of Berlin patented the use of paraphenylenediamine, paratoluidine, diamine and related compounds. In 1891 he patented the use of pyramine, benzoic acid and its derivatives especially monomethyl paraaminophenol known under the trade name of metol.

**Printing Processes.**—In turning to the positive processes the first was with silver chloride and excess of silver nitrate on plain paper which gave print with a rather sunken appearance. The image being more or less buried in the fibres of the paper and dark at the essential for printing. Blanquet Evrard in 1847 suggested the use of albumen to keep the sensitive salt more on the surface. In the same year Roumeu proposed salting with a mixture of alkaline bromides and chlorides containing gelatine and subsequent floating on silver nitrate solution. A few years later the first coat of albumen was coagulated and a second applied which gave a more brilliant glossy surface. The colour of prints obtained on these papers was an unpleasant foxy colour and to darken this an acid was added to the fixing bath thus causing sulphur toning. Le Gray in 1850 proposed the use of a gold salt to improve the colour and an alkaline gold bath was recommended by Waterhouse in 1858. De Caranza 1856 recommended the use of platinum in lieu of gold. Albumenized paper made in this way and toned with gold remained the standard photographic printing medium until 1890.

A. Caudin had suggested an emulsion of silver chloride in collodion for printing out. This was revived by Wharton Simpson in 1865. Paper thus prepared was introduced commercially by Obernetter three years later. Humbert de Molard 1855 proposed to precipitate silver chloride wash and suspend it in solution of starch or gelatine and paint the mixture on to paper. The same process was revived by Smith and Palmer in 1865 and by Abney in 1885. From this date gelatinized chloride or printing out paper came into general use and eventually completely displaced albumen. Printing out papers are at present used in Europe chiefly collodion papers containing a gold salt that obviates the necessity of toning but in America their use is limited to the production of rough proofs. Commercially they have been superseded by development papers.

Silver bromide with excess silver nitrate was used by Fox Talbot and J. W. Swan in 1839 patented the use of paper coated with silver bromide emulsion not containing excess silver for development. It did not however come into general use until marketed by Eastman and by Just in 1883. Eder and Pizzighelli published 1881 an exhaustive paper on gelatinochloride of silver with development and the former two years later described a chloro bromide emulsion. Chloride developing paper was introduced by Marion in England under the name of Alpha in 1889 and by Baekeland in America as Velox. Year by year since then the use of this paper has increased special types including a great variety of surfaces being used for amateur and professional work.

**Non silver Printing Processes.**—Robert Hunt was the first to utilize the light sensitiveness of ferric oxalate in combination with a platinum salt in the hopes of obtaining images in that metal. But the process was a failure because he did not recognize that the ferrous salt formed by the action of light must form a complex salt in order to reduce the platinum salt to the metallic state. W. Willis in 1878 introduced the first workable platinum process. The great advantage of this process is that the pictures are permanent, as platinum is one of the most resistant of all metals. A modification of the process enables a platinum deposit of a sepia colour to be obtained and for many

The first of these was the introduction of the dry plate process in 1839. This was a great improvement on the wet collodion process, which had been used since 1835. The dry plate process was simpler and more convenient, and it allowed for the production of larger and more durable prints. It was also the first time that a photograph could be taken in a single exposure, without the need for a dark room or the use of a camera.

The albumen process, which was introduced in 1850, was another significant development. It involved the use of egg white (albumen) to coat the surface of a glass plate, which was then sensitized with silver salts. This process produced very sharp and detailed prints, but it was also quite expensive and required a lot of skill to handle the materials.

The modern development of portraiture has been influenced largely by home portraiture and by the use of artificial light in the home or elsewhere. The first arose from the entry into the profession of artists usually without studio experience who believed that they could obtain more characteristic portraits in the everyday surroundings of patrons and of experienced photographers who operated over a wide field without the need of maintaining an expensive studio. This type of photography has become very successful.

Artificial light was introduced primarily to make the photographer independent of the vagaries of the weather. Since the use of artificial light made any large room suitable for use as a studio and the influence of home portraiture encouraged the replacement of artificial backgrounds and accessories by the natural surroundings of a room, the studio has lost much of its artificial character.

In a reaction from the elaborate backgrounds of the 90s many photographers employed almost perfectly plain backgrounds for portraiture, these being conspicuous in the work of Hollyer, Craig Annan and Furley Lewis in England, of Hofmeister and Perscheid in Germany, and of MacDonald in New York.

At the present time portraits of the better class are usually supplied of large size 6 X 8 in. and upwards and in folding mounts which protect the surface of the print.

In the United States negatives are taken very largely on flat sheets of portrait film developed in tanks in a vertical position and printed either by contact on developed chloride papers or by enlargement on bromide or chloro-bromide papers. The use of enlargement for making portrait prints has increased greatly owing to the introduction of automatically focusing projection printers. In Great Britain much printing is still by contact on bromide paper and on the more sensitive grades of chloro-bromide. Retouching is still used very largely in portraiture but the increasing use of panchromatic materials tends to diminish its extent.

In addition to the high grade professional portraiture discussed here there is a very large industry in the supply of cheap portraits to the masses, especially in the large cities and the pleasure resorts. The negatives are taken by artificial light on strips of film or in a camera so arranged that several can be taken on one plate and are printed as rapidly as possible on strips of paper which are usually cut to the size of post cards or even smaller. A still cheaper grade of portrait is produced by the ferrotype process on dry collodion coated on black japanned metal, this being the modern representative of the Ambrotype process. Similar pictures made with wet collodion have survived from 1860 as "tintypes".

A more recent introduction consisted of an automatic apparatus

for the production of a coin into a slot a series of photographs were produced by a reversal process a strip of film was delivered to the customer in a few minutes.

**Commercial Photography**—In addition to portraiture the photographer has been accustomed to make his money by the production of buildings, machinery or articles of interest. The requirements for commercial purposes have led to the development of a specialized group of photographers and except to a small extent it is not possible for amateur photographers.

The work of the commercial photographer is of the most varied character and may be divided into three sections according to whether the photographs are intended for use as a record, often for reference in connection with construction work, to replace samples or for use in advertising, to solicit orders or for use in advertising. In the second field the photographs are often coloured by hand a process which is almost obsolete in other branches of photography but which is rendered necessary by the absence of a cheap and satisfactory process of natural colour photography. Upon the first photographs for use in advertising may be designed either to repeat the article as in those employed for catalogues, illustrations to show the actual use of the article in the hands of the consumer and thereby to create a desire for it or merely to attract attention. This field of commercial photography gives great scope for artistic composition and has developed very greatly of recent years.

Two characteristics of commercial photography are its use of suitably trained models who are chosen with the greatest care and the employment of special means for the photography of coloured objects.

Panchromatic materials and light filters were adopted by commercial photographers as soon as they were available and a thorough understanding of their use is essential to satisfactory work at the present time. The apparatus used in commercial photography is remarkable chiefly for its adaptability and portability, it is necessary to photograph all kinds of objects in all sorts of places and only a small portion of the work can be done in the studio.

Commercial photography is growing rapidly a fact evident from the extensive use of photographs in advertisements.

**Applied and Scientific Photography**—Photography is used in science and industry primarily to make a record which can then be studied and measured. It can also be used to facilitate the copying of documents etc. photographic methods having the advantage of accuracy and speed. For this work a so-called photostat camera is used in which a roll of paper is employed on which the document is recorded (See Plate III fig 2). The result is in the form of a negative and for many purposes these negatives are satisfactory if positives are required the negatives are re-photographed in the same camera.

In addition to its use in libraries and so forth for circulating extracts from books or copies of letters and other documents photographic recording is now used very largely for the preparation of legal records especially in connection with real estate. For such purposes a special ledger paper is used coated with emulsion on both sides so that the photographs can be bound into books in the minimum space.

For the photography of ancient or falsified documents use is made of ultra violet light by means of which it is possible to decipher palimpsests, forgeries and so on.

Another application of photography to recording is that of the so-called factograph camera (See Plate III fig 3).

This camera includes a spool of sensitive paper on which the record can be made, a lens and lighting box being placed in front of it so that when the camera is pressed down on an object such as a metre dial to be photographed lamps supplied by dry batteries will illuminate it. The object will then be in focus on the paper and many records can be made in quick succession.

Another special device carrying out the same idea is that due to G. L. McCarthy, who has designed a camera intended to

PHOTOGRAPHY USED IN SURVEYING

One of a series of photographs taken with a photodolite and a contour made from them

FIG 4—SEISMOGRAMS FROM THE U.S. COAST AND GEODETIC SURVEY MAGNETIC OBSERVATORY NEAR HONOLULU, HAWAII

photograph upon a strip of motion picture film all the clock passing through a bank. This camera which is known as the Recordak provides a permanent record which really does not have the risk of fraud. A more recent form of this camera known as the News Recordak is employed to photograph newsreels on 35 mm film so providing an enormous reduction in storage space.

Special cameras have also been designed for photographing the inside of rifle barrel in order to study the erosion of the bore for lowering into oil wells in order to photograph the shaft and for use with cystoscopes to photograph the interior of the body. All these cameras involve the optical principles of the periscope (*q v*).

An interesting application of photography is the so called gun camera designed by the Royal Air Force in 1916 and used for the training of military aviators (See Plate III fig 1). With this camera which resembled in shape a machine gun an aviator in training engaged in mock combat photographed his adversary and on development the film showed the accuracy of his aim. High speed motion picture cameras enabling photographs to be taken at speeds of several thousand a second are much used for the study of fast moving mechanisms.

The greatest application of photography is however to general recording. The use of photography for recording the movement of physical instruments is mentioned as early as 1836 in Tinsanders handbook of photography. As a rule any physical instrument can be made to record photographically. Thus a galvanometer reflects a beam of light by means of a mirror the movements of which are controlled by the current in the instrument. If the light is allowed to fall on a photographic material which is moving a record will be obtained. Convenient cameras for this purpose use plates allowed to fall at uniform rates or rotating drums covered with paper or film.

A very wide application of photographic recording is found in the oscillograph which is used for many purposes in addition to its primary one of recording the wave form of intermittent or alternating electric currents.

The electrocardiograph is an oscillograph adapted to the recording of the very weak currents produced by the heart.

The applications of photographic recording are innumerable its use for magnetographs and seismographs should however be mentioned (See fig 4). When the mirror is attached to a diaphragm sound can be recorded and analysed (See MOTION PICTURES).

In connection with science photography is used (1) for recording visible images (2) for integrating radiation over long periods (3) for detecting invisible radiation (4) for measuring the intensity of radiation. Classes 1 and 2 covering the recording of visible images whether for a long or a short time cannot of course be separated and cover between them by far the most important applications of photography.

**Astronomical Photography**—One of the branches of science to which photography is of the greatest importance is astronomy. At the present time visual observation in astronomy has been replaced almost entirely by photography. A photographic plate is used in the focal plane of the telescope and the observers work is reduced to directing the telescope towards the object to be photographed and correcting any irregularities in the driving clock which would produce a shift in the position of the image upon the plate.

In the case of reflector telescopes the photographic focus is of course identical with the visual focus since mirror systems do not involve chromatic aberration and for this reason as well as because of their lower cost all modern telescopes of the largest size are of the reflecting type. A certain number of refractors have been made with photographic correction of their lenses but most of the large refractors are corrected only for visual rays and with these photography is done on green sensitive plates through a strong yellow filter so that the record is made by green light.

Stellar positions are now determined entirely photographically the micrometer eyepiece no longer being used. In this connection the astrographic chart should be mentioned (See ASTRONOMY). A notable advance made possible by photography is the accurate determination of the parallaxes of the nearer stars. The number of stars observable has been greatly extended by photographic means the 100 inch reflector at Mount Wilson recording stars of the twenty first magnitude that is about one million times fainter than the faintest stars visible to the naked eye. And it may be confidently anticipated that the projected 300 inch reflector when completed and used photographically will make a proportionate increase.

**Spectroscopy**—In spectroscopy (*q v*) visual observation has also been replaced by photography. The ease indeed with which the ultra violet and violet parts of the spectrum could be photographed has led perhaps to an undue amount of attention being concentrated on those regions. The photography of the longer wave lengths of the visible spectrum became possible only after the discovery of the isocyanine and carbocyanine dyes at the beginning of the twentieth century. Using the new sensitizing dyes discovered in 1931 and the following years it is possible to photograph the spectrum as far as 1350 mμ with ease (See Plate III fig 6).

In the ultra violet ordinary photographic plates are satisfactory down to 230 mμ but below this the absorption of the gelatine becomes serious. V. Schumann first investigated the short wave length region from 120 mμ to 200 mμ by means of plates prepared with a minimum of gelatine. Recently satisfactory photographs have been made in this region on ordinary plates sensitized with fluorescent bodies.

**Photomicrography**—The application of photography to

microscope is used for the examination of bacteria and of the structure of the minute structure of the nucleus and of the chromosomes. Biologists are now reaching to the utmost limit of the resolving power of the microscope.

Since resolving power is limited by the wave length of the light used, photomicrography with ultraviolet light is now of value. It has been used with remarkable results in the field of biology and is also being applied to the study of the minute structure of metallic alloys.

Apparatus for this purpose designed by A. Kohler was introduced by Carl Zeiss in 1914.

In the photography of stained specimens the control of the colour of the light is of great importance and for this purpose sets of light filters have been designed by means of which stains can be photographed by light exactly complementary to that which they transmit. The maximum contrast is thus obtained.

**Phototopography**—Col. Laussedat of the French army was the pioneer in the application of photography to surveying and since photographic surveying is more suitable for mountainous countries it was in the Alpine regions of Europe and the mountain chains of Canada that the largest areas were first surveyed photographically. Dr. Deville, late surveyor general of the Dominion of Canada, studied the subject very exhaustively and wrote a number of books on the subject and the Russian surveyors have also used photographic methods on a large scale especially in their surveys of Siberia.

In order to make a photographic survey two photographs are taken of the same area from different known positions which are plotted on the map. Lines are then drawn from the positions to each identifiable point on the map and object in the photograph until the complete survey is accomplished this plotting being done after the manner of a plane table survey but with the advantage that the detailed plotting is done in the office and is therefore independent of the weather the only work done in the field being the photography. The cameras used for the purpose are of rigid construction and have levelling mounts so that they can be levelled precisely. Elaborate photo theodolites have been devised for the purpose notably a beautiful instrument designed by Zeiss but simpler cameras are also quite satisfactory provided that they are rigidly made (See Plate III fig 4). No considerable area can of course be mapped without a skeleton of positions determined relatively to each other with precision and the primary triangulation is therefore made over the area to be mapped other points then being interpolated from the photographs.

Another method of photo surveying is by the use of the principle of stereoscopy. Two photo theodolites are put at the opposite ends of a measured base and exposures made in which the same objects are included. From the photographs distances can be measured by the use of the stereo comparator designed and perfected by Prof. Pulfrich of the optical research establishment of Carl Zeiss at Jena. A notable advance in this field of stereoscopic photo surveying was made when Captain von Orel of the Austrian army developed the stereo autograph which is a three-dimensional pantograph which can be used in conjunction with a stereo-comparator and will plot a map directly from the photographs. Stereo-photo topography is now the most advanced of photographic methods of survey its accuracy is high and it is very rapid. Its drawbacks are the high cost of the instruments the necessity for base measurement which is not always easy and the considerable weight to be transported (See Plate IV).

**Aerial Photography**—Photography from the air is utilized for many purposes, especially for surveying. Its use during the World War was very extensive thousands of negatives being taken every day by the armies. The first aeroplane cameras were of the type of the old camera with usually a focal plane shutter and the material was generally plates carried in holders and later in a zinc adapted for quick changing. Hand operated cameras and magazines were later developed and were used largely in 1914-1915. Later semi automatic plate cameras were developed in which the observer released the shutter while the mechanism at the same moment operated the changing of the plate. In the last years of the World War (1914-1918) these cameras were made of very considerable size as well as of very considerable weight sometimes as many as 50 plates each of which measured 18 cm X 4 cm in size and were carried in a camera at one time.

Towards the end of the World War film cameras were developed which were capable of carrying rolls of film giving 100 exposures 18 X 4 centimetres in size. The great advantage which cameras of this kind have over other cameras is of course the light weight of the material used. In the year 1918 entirely automatic film cameras were made the changing of the film and the exposure being carried out by means of a motor which might be either electrical or driven by the wind (See Plate V fig 1). Automatic film cameras are now used almost exclusively in view of their superiority over plate cameras.

From the photographic point of view the most important phenomenon encountered when working from a great height as in an aeroplane is the scattering of the light by the atmosphere an effect which is generally known as haze. Since this scattering is greater for shorter wave lengths of light it can be eliminated to a considerable extent by the removal of the blue light and by the use of only longer wave lengths. In order to accomplish this the materials used are generally sensitive to red light and filters can be used with satisfactory results as to exposure under such conditions great penetration through hazy atmosphere is possible. Excellent photographs have been taken from the greatest height reached by an aeroplane and by balloon from the stratosphere.

While aerial photography is an immense aid to the military both for the detection of enemy operations and also for the preparation of maps its application to precision surveying is subject to limitations. It is not possible to note with sufficient accuracy the height and angle of the aerial camera for a map to be made without correction for errors and consequently aerial surveying requires the provision of bases of known position on the ground which can be included and used to scale and correct the photograph. This limits its use in surveying (qv) since such measured bases are not always available. Nevertheless there are many purposes for which aerial surveying is very well adapted. A fire survey of a city can be made with sufficient accuracy by aerial photography at less than one tenth of the cost of a corresponding ground survey. This makes it possible to repeat the fire surveys of rapidly growing cities at much more frequent intervals than could be done otherwise. Surveys of lakes and forests can be carried out by the aeroplane rapidly and with sufficient accuracy for many different purposes (See ARCHAEOLOGY SURVEYING).

**Radiography** (See RADIOTHERAPY X RAYS NATURE OF)—In this branch of photography very special conditions of work are involved. From its introduction in 1896 when X rays were discovered by Röntgen the field of radiography—almost entirely in connection with its medical application—has grown until at the present time approximately as many negatives are taken by means of X rays as are made in portrait studies.

The earlier radiographs were made on plates of the same type as those used for portraiture improvements were made by the introduction of large quantities of silver salt into the emulsion while later attempts were made to load the emulsion by the addition of salts of other metals in such a way that the absorption of the X rays would be increased and high sensitiveness obtained. There is reason to believe that these attempts were based on an incorrect understanding of the laws of the absorption of the

X rays A considerable advance in the technique of X ray photography is the use of double coated film. This is a film which has a thin layer of silver coating on both sides of the film. The film is then placed in a cassette which is half on the front and half on the back. The film is then exposed to X rays. Such films in combination with one or more intensifying screens. The intensifying screens are a layer containing calcium tungstate coated on a support. The calcium tungstate fluoresces under the action of the X rays transforming a portion of the X ray into light which is active photographically. The general method of use is therefore is to expose the film in a cassette that is open on both sides which the film is pressed into contact with the intensifying screens on each side.

One of the great difficulties in obtaining radiographs of good quality especially when photographing through portions of the body of considerable thickness is the presence of scattered radiation or secondary X rays produced by the scattering of the primary X rays in the tissues. Measurements have shown that the scattered radiation generally accounts for as much as three fourths of the entire density of a radiograph taken through the body and since this scattered radiation does not contribute to the formation of the image it naturally produces a great lowering of contrast and general loss of detail and quality. The best method of eliminating this is the use of what is known as the Potter Bucky diaphragm which consists of a grid formed of strips of lead foil pointing toward the source of the X rays. This diaphragm is placed between the subject photographed and the film. In order to prevent its forming shadows the diaphragm is moved during exposure and under these conditions the strips of lead cut out much of the scattered radiation which is not proceeding from the source of X rays but is scattered in all directions and thus enable the image to be formed to a much greater extent by the direct X rays coming from the focal point. (See fig 5.)

For dental work the film is supplied in special packages to be held in the mouth usually with a backing of lead foil to stop secondary radiation and to enable the package to be moulded to the shape of the mouth. Dental radiography has been extended very rapidly and radiographs of the teeth are among the most valuable guides to the operations of the dental surgeon.

(C E K M)

## THEORY OF PHOTOGRAPHY

**The Sensitive Material**—If a photographic negative be examined under a microscope it will be seen to consist not of a continuous homogeneous surface but of discrete small silver grains occurring chiefly in clumps (*See Plate V fig 3*) These silver grains are derived from the structure of the original sensitive emulsion This is shown in Plate V fig 4 where we see that the developed grains correspond in general form and position to the undeveloped silver bromide grains from which they were produced

If the emulsion is removed from a sensitive film and spread out under a microscope in a thin layer it will be seen that the silver bromide is in the form of crystals these being usually flat crystals generally hexagonal or triangular in shape (*See Plate V fig 5*) These crystals are very small  $\frac{1}{1000}$  in or less across, there are great numbers of them in a film several thousand million in a square inch, and their size depends upon the way in which the emulsion was made

If an emulsion is made by adding a solution of silver nitrate

FIG 5—DIAGRAM SHOWING USE  
OF POTTER BUCKY DIAPHRAGM

[illegible]

The sensitivity observed depends to a very large extent upon the particular kind of glass used. Some gelatine giving high sensitivity while other simple applications of the same chemical and physical properties will not give good sensitiveness. However long the heating is continued it will be shown later that this has been found to be due to a small impurity carried in the gelatine.

The crystals in an emulsion vary very greatly in size their size and distribution being controlled by the conditions under which the emulsion is precipitated and distilled. The sizes of rain which occur in an emulsion are directly connected with photographic properties of that emulsion.

When the grains cover a wide range of sizes the emulsion is suitable for making negatives; it usually has a high degree of sensitiveness and a low degree of contrast. When on the other hand the grains are small and uniform the emulsion has a high degree of contrast and a low sensitiveness; such emulsions being used for positive film or lantern slide making.

If we suppose that the same amount of photo chemical product (latent image) makes either a large or a small grain developable, then other things being equal the larger grain contributes a larger amount of silver to the image and thus gives more density for the same amount of light action than a smaller grain. For this reason alone emulsions containing large grains would be more sensitive than those containing small grains but experiment has shown that this is not the only factor and that on the average larger grains require less light action to become developable than small grains. Further it has been shown that the seat of this sensitiveness is concentrated in specks in the grains and the sensitiveness of the grain depends upon the presence and the number of these sensitive specks.

Since they differ in nature from the silver bromide it was suspected that the specks were derived from the gelatine since some gelatines give emulsions which are much more sensitive than others. A material was extracted from gelatine which was identified by Dr S E Sheppard with allyl mustard oil which in ammoniacal solution becomes allyl thiocarbamide. Allyl thiocarbamide reacts with silver bromide and the compound of the two in alkaline solution produces silver sulphide so that the sensitizing specks may consist of minute traces of silver sulphide on the surface of the silver bromide grain. The ripening process in the preparation of gelatine bromide emulsions may therefore be ascribed partly to the growth of grains of larger sizes from those of small dimensions and partly to the production of the sensitizing specks of silver sulphide on the surface of the grain. Silver itself may also be associated with the specks.

The exact action of light upon the silver halide and the nature of the product which renders the grains developable is not well understood although recent work is tending to define the issue and to suggest that we are not far from the complete solution of the problem. The exposed silver halide which changes to silver in development is known in photography as the latent image and the problem of the nature of the latent image has been a

[illegible]

The latent image character in developing silver proper. I form possible since it has been known open to the air. As I found in the first part of the investigation, the deposition of silver in a reducing agent such as a developer can be destroyed by powerful oxidizing agent such as chromic acid or acid permanganate. The properties seem to call for the existence of some definite chemical individual and I would appear therefore that the latent image must consist of some reduced product of silver bromide. Those which have been suggested are silver sub-bromide and metallic silver.

The existence of silver subbromide is doubtful. The formula  $\text{AgBr}$  has been proposed but it has never been prepared in a pure state. All attempts to prepare it have resulted in mixtures or solid solutions of silver bromide with metallic silver. While the theory that silver subbromide was the material of the latent image was accepted for many years it is now generally agreed that the image consists of metallic silver in very small amounts formed by the reduction of silver bromide.

When light falls upon a crystal of silver bromide therefore it produces a small quantity (perhaps a few hundred or a few thousand atoms) of silver. The size or condition of this speck of silver determines whether or not it will act as a nucleus to make the crystal developable. The production of the silver appears to be greatly facilitated by the existence on the crystal of small specks of foreign material presumably from Shppard's work mainly silver sulphide. The mechanism of this action is still under discussion.

Dr Sheppard and his colleagues have developed a theory which they term the concentration speck theory according to which the action of the sensitizing speck is to concentrate the energy falling upon the silver bromide and enable silver to be liberated at the boundary of the speck. Toy and Trivelli have suggested independently that the chief action of light is to increase the conductivity of the silver bromide and Trivelli suggests that an electrolytic action then ensues as a result of which metallic silver is deposited in contact with the silver sulphide speck. Hickman and others have postulated that a sensitizing speck must be an acceptor for the halogen set free and many mechanisms have been suggested for the reaction. Much work remains to be done on this problem however.

**Development**—In the process of development the bromine is removed from the crystals of silver bromide which are transformed into coke like masses of metallic silver. With some developers the silver takes the form of the silver bromide grains while with others the grain is entirely broken up and distorted and is merely replaced by an equivalent amount of metallic silver (See Plate V figs 6 7 8). There are many chemicals which will reduce silver bromide to silver but in order to act as a developer it is necessary that the solution should have the power of turning exposed silver bromide into metallic silver and should not be able to act on unexposed silver bromide since if the solution acted on the unexposed as well as the exposed grains the whole film would darken and we should not get an image at all. Only a very limited number of substances have the power of distinguishing between exposed and unexposed grains of silver bromide, and there are therefore only a few substances which are suitable for use as developers. With the exception of ferrous oxalate and one or two other inorganic compounds which have fallen into disuse all the developing agents used are phenolic or amino compounds derived from benzene or naphthalene.

The chief developing substances are pyrogallol or *pyro* as the photographer calls it, hydroquinone and methylparamino phenol, which is known under trade names such as "metol" and "eikon." All of these developing substances are chemically related

to benzene  
it was however by Lumiere and Seyewetz and by Andresen  
in order to be practically useful developers must contain  
a radical group or amino groups or one hydroxyl  
group in order to be attached to the benzene nucleus in the para  
position. These compounds have no developing power  
The hydroquinone derivatives chiefly used are thus hydroquinone

which is prepared by oxidation of aniline and the reduction of the quinone formed metol or methyl paraminophenol.

which can be produced by the methylation of paraminophenol or by various other direct reactions and pyrogallol trihydroxybenzene

which is produced by the distillation of gallic acid

In addition to these three there are a large number of similar compound which can be used as developing agents and for which advantages are sometimes claimed. In all probability however the three compounds given above will supply all the needs of the photographer.

Two compounds which have some wide use however are  
p-aminophenol

which is intermediate in its properties between methylparamino phenol and hydroquinone and diaminophenol or amidol which is used for the development of papers

With the exception of diaminophenol these compounds are unable to reduce silver bromide in neutral or acid solution and in order to make a developer alkali must be present in the solution. On the other hand in the case of the aminophenols the developing agents are used in the form of salts of the bases thus metol is the sulphate of methyl paraminophenol and it is usual to employ the chloride of paraminophenol and of diaminophenol. Enough alkali must therefore be added initially to liberate the base itself which is usually insoluble in water and to redissolve it as the alkaline phenolate. The most convenient alkali is sodium carbonate and a typical developer would thus consist of pyrogallol with sodium carbonate added to it. As is well known however alkaline pyrogallol absorbs oxygen from the air very rapidly and would soon darken and lose its developing power. In order to make a developer keep a small quantity of sodium sulphite is added to the solution. The sulphite protects the developer from oxidation and thereby enables it to retain its full developing power although the sulphite when used alone possesses no developing power whatever.

The essential constituents of a developer therefore are the developing agent—pyro hydroquinone or metol the alkali, which is generally sodium carbonate and the preservative which is sodium sulphite. In addition it is usual to add a small amount of alkaline bromide which will act as a restrainer and prevent

the development of unexposed liver and  
what is known as for

The various developing agents have been compared. Suppose for instance that we make up a solution of hydroquinone and the other with metol and develop a film in each at the same time. In the metol developed film the shadows will appear very quickly and will appear almost at the same time the less exposed portions. In the hydroquinone the shadows in the picture appear gradually and the highlights. On the other hand in the hydroquinone image will appear more slowly and the highlights or the highlights will appear more slowly. If the shadows have appeared on the surface of the film the highlights will have acquired considerable density. If the development is stopped as soon as the whole image is out and the film developed in metol will be very thin and grey all over. If developed in hydroquinone will have a good density in the highlights. Thus of the two developers metol gives detail first and then slowly builds up the density with hydroquinone the detail comes only after considerable density has been acquired. It is for this reason that the best developing agents are used in combination the hydroquinone increases the density and the metol the detail and together they make a satisfactory developer.

These differences in the behaviour of developing are due to a property of the developer which is common to all in photography as the *reduction potential*

The reaction of development may be represented by the following general equation —

The sodium salt of the reducing agent symbolized by R react with silver bromide and forms metallic silver the oxidation product of the developing agent which is symbolized by R and sodium bromide.

The reaction will go in either direction according to the driving force available and in practice quinone the oxidation product of hydroquinone together with sodium bromide will bleach a silver negative transforming the metallic silver into silver bromide. Now the driving force in the direction from left to right depends upon the reduction potential of the developer. This is opposed by the reaction in the opposite direction which is dependent on the concentration of soluble bromide and of developer oxidation product in the solution so that if the bromide be increased the rate of the reaction will be lowered. It is thus possible to measure the reduction potential of a developer by the effect of potassium bromide on development as was originally suggested by S E Sheppard. A careful study of this was carried out by A H Nietz who gives what are probably the most reliable data for the developers as follows —

Developer	Relative energy
Ferrous oxalate	0
p phenylene diamine hydrochloride (no alkali)	0.3
p phenylene diamine hydrochloride (alkali)	0.4
Hydroquinone (standard)	1.0
p phenylglycine	1.6
Hydroxylamine	0
Toluidine	2
p aminophenol (hydrochloride)	6.0
Chlorhydroquinone	7.0
Dimethyl p aminophenol (sulphate)	10.0
Monomethyl p aminophenol (sulphate)	0.0
Diaminophenol	30.40

A developer much used for negative making was pyrogallol. Owing to the fact that pyro is changed during development into a yellow substance some of which remains associated with the silver in the image pyro tends to give a slightly yellowish image which has very much greater printing power than the plain silver image. The yellowish stain is prevented from forming by sulphite so that the more sulphite there is in a developer the less colour the deposit will show. Pyro is, therefore, used only for the development of negatives, prints on paper or positive films in motion picture work being developed with metal and hydro

chlorinated compound to replace pyrolysis  
or gas chromatography.  
The chlorinated compound is bromide  
which has the same effect as  
the other compounds are

posed grain react to be developed and then as development proceed the exposed grains are turned into grains of black silver so that the number of developable grains decreases during development until at last there are no developable grains left all those which can be developed have been acted upon and the development of the image ceases. The rate at which the grains develop depends upon the number of exposed but undeveloped grains left and as the grains are developed and the number of undeveloped grains remaining becomes less fewer and fewer grains develop in each minute until finally it is not worth while to prolong the development in order to get an more density. (See fig. 6)

The growth of the image during development is referred to as a growth of density that is to say the density is a measure of the number of grains of silver which are produced at any given point. The e grains of silver after the film has been cleared by the fixing bath obstruct the passage of light through the film.

The density of an image is measured in units which are based on the amount of silver which will let through  $\frac{1}{10}$  of the light so that if only  $\frac{1}{10}$  of the light falling on the negative gets through a certain part of it that portion of the negative is said to have a density of 1. Similarly when only  $\frac{1}{100}$  of the light incident is transmitted that part of the negative is said to have a density of 2. The blackest part of a negative may have a density of perhaps the middle tones 1 or less and the shadows perhaps  $\frac{1}{10}$ . (See fig 7)

which is followed for copying purpose or for making a normal print. The developer is used in the same way as the fixer. The rate of development is increased by increasing the temperature of the developer. The rate of development is also increased by increasing the concentration of the developer. The rate of development is also increased by increasing the time of development.

FIG 8—THE GROWTH OF CONTRAST DURING DEVELOPMENT

the relation between the time of development and the temperature are in common use in photography. Fig 10 shows such a curve supplied for use of X-ray workers giving the time of development for a standard developer at various temperatures.

**After Processes**—After development the undeveloped silver bromide is removed by immersion of the negative or print in what is called the fixing bath. There are only a few substances which will dissolve silver bromide and the one which is universally used in modern photography is sodium thiosulphate  $\text{Na}_2\text{S}_2\text{O}_3$  which is known to photographers as hyposulphite of soda or more usually as hypo—the name hyposulphite of soda being used by chemists for another substance. Cyanide is used as the fixing bath in the wet collodion process because it will dissolve silver iodide while thiosulphate will not. It is not desirable for use with gelatin bromide plates however.

A negative or print transferred to the fixing bath invariably carries some developer with it and if this developer accumulated in the bath it would cause stain or fog. It is customary therefore to add acid to the fixing bath to neutralize the alkali from the developer and prevent this action. If free acid is added to a thiosulphate solution it is decomposed forming sulphur. This can be prevented however by the addition of sulphite which preserves the bath. Weak acids are used so that a relatively large quantity can be employed without making the bath too acid. Acetic acid is generally used. Materials are also added to the fixing bath to prevent softening of the gelatin. The commonest is alum and a typical fixing bath therefore contains 0% to 30% of its weight of hypo about 1% of anhydrous sodium sulphite

FIG 9—THE GREATEST CONTRAST WITH DIFFERENT EMULSIONS

and of potassium alum and 3% of 28% acetic acid. The developer alkali carried over by the negatives or prints to the fixing bath tends to neutralize the acetic acid and eventually may cause a sludge of alumina to form in the bath and decrease its ability to harden. This tendency to sludge can be reduced by adding boric acid to the fixing bath. This also extends the hardening life of the solution.

The rate of fixing depends upon the concentration of the hypo and on the temperature. It increases to a maximum with about 40% hypo and decreases with stronger solutions owing to a de-

crease of the swelling of the gelatine and consequent difficulty of penetration.

A very important operation in photography is the washing of the negative and prints in order to remove from them the chemicals of the fixing bath. If an exhausted fixing bath has been used, other compounds will be present during washing and it is most important that they should be removed by complete washing.

The rate of washing depends largely upon the rate of diffusion of hypo out of the film into the water provided the water in contact with the material is continuously removed. In washing

FIG 10—GRAPH SHOWING TIME OF DEVELOPMENT FOR X RAY FILM AT VARIOUS TEMPERATURES

the amount of hypo remaining in the gelatine is continually halved in the same period of time as the washing proceeds. An average negative for instance will give up half its hypo in two minutes so that at the end of 2 min half the hypo will be remaining in it after 4 min one quarter after 6 min one eighth after 8 min one sixteenth 10 min one thirty second etc. It will be seen that in a short time the amount of hypo remaining will be infinitesimal. This however assumes that the negative is continually exposed to fresh water which is the most important matter in arranging the washing of either negatives or prints.

**Reduction**—When a negative is too dense it is sometimes reduced. By reduction in photography is meant the removal of some silver from the image so as to produce a less intense image. Thus in the case of an overdeveloped plate there will be too much density and contrast and the negative may be reduced to lessen this. In the case of an overexposed negative there may not be an excess of contrast but the negative will be too dense all over and in this case what is required is the removal of the excess density.

All the photographic reducers are oxidizing agents and almost any strong oxidizing agent will act as a photographic reducer and will remove silver but various oxidizing agents behave differently in respect to the highlights and shadows of the image. Reducing solutions can be placed in three classes—

- A Cutting reducers
- B True scale reducers
- C Flattening reducers

A The cutting reducers remove an equal amount of silver from all parts of the image and consequently remove a larger proportion of the image from the shadows than from the highlights of the negative. The typical cutting reducer is that known as Farmer's reducer. This consists of a mixture of potassium ferricyanide and hypo the potassium ferricyanide oxidizing the

exposure in the instrument from  $C$  to  $D$  is a method more efficient than the previous one in the direction of over-

Proportion of the total exposure of the plate is the same as the proportion of the total exposure of the plate. The proportion of the total exposure of the plate is the same as the proportion of the total exposure of the plate.

Hurter and Driffield have adopted 4 and proposed for the purpose of the standardization of the photographic process a standard of exposure of 18 seconds at a distance of 100 cm. The standard of exposure is the same as the proportion of the total exposure of the plate. The proportion of the total exposure of the plate is the same as the proportion of the total exposure of the plate.

The permeability of the film is quite obsolete and a standard light source the character of the source to be adopted is of great importance since its photographic effect will depend upon its colour. One candle power of daylight has more than ten times the photographic effect of one candle power of light from a permitt candle. As most plates are exposed to daylight it might be assumed that this should be the standard adopted but the practical difficulty of ensuring a constant illumination of constant spectral composition are insuperable. The standard candle is notably poor in ultra violet violet and blue radiations being distinctly yellow in colour. The same objection applies to the Hefner Alteneck amylo acetate lamp which was used in Germany as standard.

It is impossible to examine in detail all light sources suggested but it has now been agreed to use a lamp standardized to work at a colour temperature of 5600 K with colour filters to reduce its spectral composition to the equivalent of sunlight.

The spectral composition of the light is all important in view of the ever increasing employment of colour sensitive materials.

As was shown originally by Abney an intermittent exposure does not give the same effect as a continuous exposure for the same total time. The use of a rapidly rotating sector is therefore undesirable and instruments giving continuous exposures should be used.

Another important factor is the failure of the reciprocity law  $E=It$ . As was first shown by Abney (*Proc Royal Soc* 54 pp 143-147, 1894) the effect of an exposure is not independent of

FIG 12—GRAPH SHOWING RELATION BETWEEN DENSITY AND INTENSITY  $It$  BEING CONSTANT

the intensity. Recent work has shown that the curve showing the relation between density and intensity  $It$  being constant has a maximum this point being referred to as the 'optimum intensity' (See fig 12). The shape of the curve as well as its absolute values vary with the type of the emulsion and also with the wave length of the light that is used. The work of Jones Hall and Webb has shown the great importance of the reciprocity law in sensitometric work.

It is therefore reliable that exposure in sensitometric instrument should only be continuous but of the intensity level that is to be determined.

The original proportion with two light sources used by Hurter and Driffield has been superseded by various optical instruments for measuring the densities and these in turn appear likely to be superseded by physical photometers such as those employing photoelectric cells. The density obtained depends on whether

FIG 13—CHANGE OF DENSITY AND GAMMA WITH TIME OF DEVELOPMENT

it is read in contact with a diffusing screen such as opal glass or whether it is observed by parallel light from a collimator. With the latter as was pointed out by Abney Chapman Jones and Callier much of the incident light is scattered so that the density has a higher value than when measured by completely

diffused light. The ratio between  $\frac{\text{density of parallel light}}{\text{density of diffused light}}$  was

termed  $Q$  by Callier it varied in amount from approximately unity to values as high as 1.6. The value of  $Q$  for average negatives is about 1.4.

Recently graduated wedges of neutral tint have been used very largely in sensitometry both for exposing and for the measurement of densities.

A point of considerable importance in speed determination is that of the fog inherent in the emulsion and developed without light action. Hurter and Driffield assumed that this was constant throughout all densities or in other words through all exposure periods but such is not the case there being actually more fog in the underexposed parts than in the more exposed parts because there is less silver bromide available and also more bromide set free here than in the less exposed parts.

Returning to fig 11 it will be observed that the tangent of the angle at which the straight line meets the exposure axis is marked  $\alpha$ . This angle is of great importance in photography since it defines the contrast of the image. The tangent of the angle that is the slope of the straight line was termed  $\gamma$  by Hurter and Driffield and was called the development factor since its value depends upon the time of development. During development the value of  $\gamma$  increases the increase tending to reach a limiting term gamma infinity ( $\gamma_{\infty}$ ) which measures the extreme contrast of which a plate is capable. Thus if we develop for different times plates which have been given a series of exposures increasing in geometrical proportion measure the densities and plot the resulting curves we shall get the result shown in fig 13 in which are shown curves corresponding to development times of 1 min, 2 min, 3 min, 5 min and 6 min while  $T_{\infty}$  corresponds to the maximum development that can be given before the contrast diminishes owing to fog.

If now we plot  $\gamma$  or density as a function of time we get a curve of the type shown in fig 14. It will be seen that the value of  $\gamma$  increases rapidly at first and then more slowly, finally reaching a limit  $\gamma_{\infty}$ . This is an exponential curve, the rate of development

the exposure is but a point somewhat below it the effect of bromide being equivalent to a constant depression of density in the straight line portion of the curve (See fig 15)

The photographic characteristics of printing papers can be measured by a procedure similar to that used for negative material but in this case it is not the mass of reduced silver which is of chief importance but its relative reflecting power. The reflection density is plus the logarithm of the reciprocal of the reflecting power ( $D = \log (1/R)$ ) the reflecting power being measured with illumination at 45° to the plane of the paper. The characteristic curves obtained with different times of development are shown in fig 16 and it will be seen that the effect of increase in time of development is to produce a regression of the inertia without changing  $\gamma$  except in the very earliest stages where the curves are usually of a distorted form. The following constants may be derived—

FIG 14— $\gamma$  CURVE SHOWING GROWTH OF WITH INCREASING TIME OF DEVELOPMENT

the exposure is but a point somewhat below it the effect of bromide being equivalent to a constant depression of density in the straight line portion of the curve (See fig 15)

The following constants may be derived—

Constant	Symbol	Significance
(a) Maximum reflection density	$D_{\max}$	Highest attainable density
(b) Contrast element (reflection density)	$\frac{dD}{d \log I}$	Differential
(c) Gamma element (reflection density)	$\gamma_r$	Value of (b) for straight line portion or at inflexion point
(d) Latitude element (reflection density)	$L$	Range of intensities reproduced on straight line portion
(e) Rendering power (reflection density)	$R$	$\frac{10I}{S}$
(f) Total scale (reflection density)	$S$	Range of intensities reproducible by density differences
(g) Standard exposure (reflection density)	$E_s$	The exposure in m.c.s. necessary to print through a negative density of 2.0

**Tone Reproduction.**—When a photograph of a natural object is made the form can be represented only by differences in brightness. The accuracy with which the form is represented depends upon the precision with which the tones of the original subject are

FIG 15—BROMIDE DEPRESSION CURVE BROMIDE IN THE DEVELOPER CAUSES A DEPRESSION OF THE CONVERGENCE POINT

to the physical brightness throughout a wide range it is generally sufficient for tone reproduction in photography to deal with the physical tones in the original and the reproduction.

The differences in brightness which occur in nature may be produced by difference either in the reflecting power of the different portions of the subject or by differences in the illumination. Since in natural scenes both the reflecting power and the illumination vary some part of a landscape consisting of clouds in sunlight and others of dark rocks in the shade the range of contrast is often very considerable. For photographic purposes a scale of contrast of 1 to 4 in which the brightest thing is only four times as bright as the darkest is very low and such a subject would be called flat. A contrast of 1 to 10 is a medium soft contrast 1 to

FIG 16—CHARACTERISTIC CURVE OF PAPERS WITH INCREASING TIMES OF DEVELOPMENT INCREASING TIME OF DEVELOPMENT PRODUCES REGRESSION OF INERTIA WITHOUT AFFECTING  $\gamma$  EXCEPT DURING INDUCTION PERIOD

20 a strong contrast 1 to 40 very strong and 1 to 100 an extreme degree of contrast. All these degrees of contrast occur in subjects such as landscapes, street and seashore scenes.

When a photograph is made, the operation is done in two separate steps. A negative is first made in which all the tones of the original are inverted, the brightest part of the subject being represented by the deposit of silver in the negative which lets through the least amount of light, and the darker parts represented by the transparent areas. This negative is then printed upon a sensitive paper to form a print in which the scale of tones is again reversed.

Introduction of the principle of the original  
 reproduction of the original image in a  
 photograph is usually horizontal and vertical  
 and the image is reproduced in a  
 photograph in a horizontal and vertical  
 direction.

The reproduction of the original image in a  
 photograph is usually horizontal and vertical  
 and the image is reproduced in a  
 photograph in a horizontal and vertical  
 direction. The reproduction of the original  
 image in a photograph is usually horizontal  
 and vertical and the image is reproduced  
 in a photograph in a horizontal and vertical  
 direction.

As a consequence of the fact that the straight line portion of a  
 paper curve is usually horizontal and vertical and the image is reproduced  
 in a photograph in a horizontal and vertical direction, the reproduction of the  
 original image in a photograph is usually horizontal and vertical and the image  
 is reproduced in a photograph in a horizontal and vertical direction.

The computation of the tone reproduction given in any photo-  
 graphic operation is of great importance especially in the appli-  
 cations of photography such as processes of colour photography or  
 of the reproduction of sound and for the methods which are used  
 the papers by F. F. Renwick and L. A. Jones should be consulted.

**Resolving Power**—The resolving power of photographic mate-  
 rial may be defined as the closeness of two adjacent images  
 which can be just distinguished. It is limited primarily by what is  
 termed the irradiation or spreading of the image due to diffusion  
 of the light in the film. This spreading of the image has been  
 investigated by astronomers and used as a basis for a method of  
 telluric photometry (See PHOTOMETRY, CELESTIAL and PHOTOG-  
 RAPHY, CELESTIAL).

In addition to the irradiation factor the resolving power de-  
 pends upon the development factor attainable in the material. The  
 sharpness of an image in fact is theoretically equal to the devel-  
 opment factor divided by the turbidity factor. Both of these fac-  
 tors are functions of the wave length of the light used in ex-  
 posure so that the resolving power is naturally dependent upon  
 the colour of the light. In addition to these two factors a psy-  
 chological factor enters into the resolution of the image.

The practical resolving power of photographic materials can be  
 measured by photographing (see fig 17) and measuring the extent  
 to which the lines are resolved.

Photographic images on devel-  
 opment show with low power  
 magnification as used in projec-  
 tion and enlarging a granulation  
 which is objectionable in such op-  
 erations. L. A. Jones and N.  
 Deisch have shown that it may  
 be measured and numerically

expressed on the assumption that the graininess is directly pro-  
 portional to the distance at which it becomes just visually imper-  
 ceptible this being compared with the distance at which a structure  
 of known period e.g. a fine cross line screen just disappears.  
 Suppose a screen of 2000 lines to the inch to be equivalent in  
 this way to a given granularity of the developed image the latter  
 may be said to have a graininess of 2000.

**The Photography of Coloured Objects.**—Since photography  
 makes a black and white reproduction of the tones of natural  
 objects all of which are to some extent coloured the way in

which their colour is reproduced in photography is of con-  
 siderable importance. The earlier photographic materials were  
 sensitive only to violet and ultra violet light and if an object con-  
 taining blue, green and red was photographed the greens and  
 red were rendered dark while the blues were rendered much  
 lighter than they appeared to the eye.

Following Vogel's discovery of the sensitizing power of dyes  
 this inaccuracy in rendering was to some extent mitigated by the  
 introduction of so-called orthochromatic materials which how-  
 ever were sensitive only to the yellow green in addition to their  
 normal blue violet and ultra violet sensitiveness and were therefore  
 unable to render the full scale of colours as seen by the eye.

At the production of the isocyanine and carbocyanine sensi-  
 zers panchromatic plates were introduced sensitive to the whole  
 visible spectrum. These plates still retain the high sensitiveness  
 to blue violet and ultra violet characteristic of photographic  
 materials generally but by the use of light filters (q.v.) with  
 them it is possible to obtain an orthochromatic rendering that is  
 one in which the reproduction of the different colours follows very  
 closely their relative brightness as they appear to the eye. This  
 is accomplished by the use of a yellow filter which absorbs all of  
 the ultra violet and most of the blue violet reducing the effective  
 sensitivity of the material approximately to that of the eye.

By the use of yellow filters therefore and panchromatic plates  
 and films approximately correct colour rendering is now used very  
 largely in practical photography. Sometimes however subjects  
 have to be photographed which are visible to the eye by virtue of  
 their colour contrast. Suppose we have two objects one contiguous  
 to the other and separated purely by their colour contrast such  
 as for instance a yellow straw stack against a deep blue sky. In  
 this case orthochromatic rendering would produce a photograph in  
 which both would have the same intensity and they would be  
 indistinguishable. It is necessary in this case to use a colour filter  
 which will introduce a certain amount of incorrect rendering in  
 order to reproduce the colour contrast. This filter may for in-  
 stance be a red filter in which case the straw stack will appear  
 brighter than the sky or it may be a blue filter in which the sky  
 will appear brighter than the stack. The choice of such filters is  
 an important task for the skilled photographer. Contrast filter  
 are used very largely in photography for special purposes. They  
 are of great value in photomicrography and are used in commercial  
 photography to a large extent. The deepest possible filter is also  
 used in aerial photography in order to take advantage of the power  
 of the longer wave lengths to penetrate haze. (C. E. K. M.)

FIG 17—FAN TEST OBJECT USED

 POWER OF PHOTOGRAPHIC MAT-  
 ERIALS

## PHOTOGRAPHIC MANUFACTURE

The manufacture of photographic sensitive materials is a very  
 specialised industry. Approximately 40 000 people are employed  
 in the whole photographic industry throughout the world about  
 10 000 being engaged in the manufacture of materials sensitive  
 to light with which this section deals and the remainder in the  
 manufacture of cameras and in the wholesale distribution of the  
 products to the retailer.

With the introduction of the gelatine dry plate the preparation  
 of materials by photographers for themselves diminished very  
 rapidly and the manufacture of ready prepared material took its  
 place. The first dry plates appear to have been placed upon the  
 English market in 1877. In 1880 the manufacture of gelatine dry  
 plates was general in England and was commencing in Belgium,  
 Germany, France and the United States.

Until 1900 the photographic industry was usually carried on  
 in small factories under the direct personal control of the founder.  
 At the present time however photographic manufacture is or-  
 ganised chiefly in modern factories manufacturing on a large scale  
 and using specially designed machinery at every step of the pro-  
 cess. In the largest of these factories the output of motion  
 picture film alone exceeds 150 000 miles yearly. Over 5 000 000  
 lb of cotton are used each year for the manufacture of film and  
 over three tons of pure silver bullion are used each week. The  
 total power required exceeds 20 000 h.p. and the consumption of  
 coal is over 500 tons a day.

The process of manufacture may be divided into three distinct

### Preparation of the Base

The first step in the preparation of the base is the cleaning of the glass plates. The plates are first cleaned by an automatic machine in which they are passed through a series of brushes and then through a solution of soda between revolving brushes which remove the dirt from the surface and at the end of the process are coated with a substrate usually a weak solution of gelatin containing chrome alum by means of which the emulsion may adhere to the glass. The glass is then dried in a heated oven examined for defects and if passed is packed in a tray and transferred to the coating room.

**Film Base.**—In the manufacture of film base the first step is the preparation of cotton linters for maturing the treatment consisting of cleaning the linters very thoroughly and drying them. They are then nitrated in centrifugal machines and when they have absorbed the nitrates amount of nitrogen 1 to 1.5% the resulting nitro cotton is soaked in water and the washing commenced. This washing is a long process and is continued until the material is entirely free from absorbed acid after which it is dehydrated the water being then displaced by alcohol. The dehydrated nitro cotton is then dissolved in tumbling barrels or mixers in suitable solvent these commonly employed being acetone and methyl alcohol and at the same time the so called softeners such as camphor are added these resulting in a flexible film. The viscous nitro cotton solution which appears rather like honey is known in the United States as dope. This is now spread out into a thin film by coating it on a travelling surface. In the United States the coating is generally done on large wheels about four feet across and about fifteen feet in diameter which rotate slowly about their axes so that by the time one rotation is completed the solvents have been evaporated sufficiently to set the film which can be stripped off the wheel and dried further by passing over drums. The operation is thus continuous the film base as it is called being prepared in rolls of about 2000 feet. In Europe it is customary to coat a film about 4 inches wide upon a metallic belt from which after one rotation the film can be stripped in the same way as from a drum. The surfaces of these belts and drums must necessarily be prepared very carefully the wheels being usually made with a highly polished nickel surface while the makers of the belt machines recommend that they be coated with gelatine. The film has a high polish on both surfaces and may be used at once or stored or seasoned until required. Before coating with emulsion one side is treated with a substratum which is really an etching solution that slightly roughens it and gives a tooth that holds the emulsion firmly. For camera film the back is coated with a non curling coat of hardened gelatine which imposing an expansion strain on this side equalizes that of the emulsion on the other. Camera or roll film base is about  $\frac{3}{4}$  thousandths of an inch thick motion picture film about  $\frac{5}{16}$  thousandths and cut film such as portrait and X ray which are used flat about  $\frac{7}{16}$  thousandths. Still thicker cut films are sometimes used about 10 thousandths but the celluloid for these is cast into blocks and then sliced the knife marks being removed by heat polishing.

Since cellulose nitrate is highly inflammable itself supplying the greater part of the oxygen which it requires for combustion much work has been done on the preparation of film which is not inflammable. The most promising substance for this purpose is cellulose acetate prepared by treating hydrated cellulose with acetic acid and acetic anhydride in the presence of a suitable cata-

lyst. The paper is usually given a coating of baryta before it receives the photographic emulsion. In this process a suspension of baryta (barium sulphate) in gelatine is coated over the surface of the paper several coatings being sometimes applied and not infrequently the paper is calendered after baryta coating in order to get a perfectly smooth glossy surface. Baryta coated paper is transferred to the emulsion coating room in rolls of about 1000 feet.

**Emulsions.**—Emulsions are of two general types washed and unwashed. Emulsions to be coated on glass or film are always washed. In the first case the precipitation of the silver salts is effected by adding a solution (about 10% in strength) of silver nitrate to a small quantity of gelatine dissolved in a solution of the halide salts which in the case of negative emulsions are usually potassium bromide containing a small proportion of potassium iodide. When precipitation is complete the emulsion is digested in order to produce an increase of sensitiveness and the bulk of the gelatine is added so that when cooled it will set to a jelly. Instead of increasing the sensitiveness of the emulsion by holding it at a high temperature for some time it may be digested at a lower temperature in the presence of ammonia and not infrequently the silver nitrate is precipitated with ammonia and then redissolved in excess before the precipitation of the halide is commenced. The set emulsion is cut up into small portions and is washed in running water in order to remove any excess of halide salts and also the soluble nitrate produced in the reaction. After washing it is given a final digestion and is ready for coating upon the base.

The emulsions used for printing papers are of three general types bromide papers which are made with a washed emulsion essentially identical with that used for coating upon glass and film for use in making lantern slides and positive motion pictures unwashed chloride emulsions in which the emulsion is coated on the paper in the form in which it is mixed without any removal of the soluble salts by washing and emulsions also made without washing but in which the silver salts are a mixture of chloride and citrate and in which there is free silver nitrate present. These papers darken visibly when exposed to light and thus give a printed out image which is then toned and fixed.

**Coating and Packing.**—Dry plates are coated by passing the

The camera or cartridge film is slit to the required widths cut

The practical development of colour photography was, however, delayed for many years by the difficulty that the photographic materials available were sensitive only to the blue and violet of the spectrum it was with the greatest difficulty that materials sensitive to the whole visible spectrum could be obtained and with such materials very long exposures were required.

The additive process is a method of producing colour photographs by the superposition of three separate images, each of which is a monochrome photograph of the same subject, but taken through different colour filters.

**The Additive Process—**Colour photographs can be made by the additive process. This involves the use of three separate photographic plates, each of which is exposed through a different colour filter. The three plates are then superimposed on each other, and the resulting image is a colour photograph.

The first step in the additive process is to take three separate photographs of the same subject, each through a different colour filter. The filters used are usually red, green, and blue. The three photographs are then superimposed on each other, and the resulting image is a colour photograph.

The production of the negatives can be accomplished by the three-plate method. For stationary objects where an interval between the exposures is of small importance it is convenient to fit the filter and sensitive plate in one sliding back attached to a motion picture camera. Exposures are then made through the three filters in succession either upon a single panchromatic plate or on three separate plates.

For the photography of moving objects it is of course impossible to use successive exposures and a great number of cameras embodying beam-splitting methods either by means of prisms or by reflection have been designed. The chronocope already referred to as a viewing instrument can be converted into a camera in which mirrors are used for separating the three beams. Other cameras use elaborate combinations of prisms for the same purpose. In such cameras it is often convenient to use separate plates since it is rather difficult to arrange for the three images to fall upon a single surface.

A system invented originally by du Hauron is to have the sensitive surfaces superposed on each other and to build up a plate or film pack, thus in front there may be placed a slow very transparent yellow dyed blue sensitive film behind this a moderately transparent film sensitive to green and dyed red or with a red filter attached to it behind this again a red sensitive film. In this way the blue record is made on the first film the green record on the second and the red on the third. A considerable number of patents have been taken out for variants of this method.

**The Subtractive Process—**The subtractive process which was described originally by du Hauron depends upon the production of colours by subtractive absorption instead of by the addition of the colours to each other in projection. Suppose that over a sheet of yellow gelatine which will absorb the blue light is put a sheet of magenta gelatine which will absorb the green light then since the yellow absorbs the blue light and the magenta the green light only the red light is transmitted a red image can thus be obtained either by projecting it through a red filter or by putting a magenta image on the top of a yellow one. In the same way a green image can be obtained by putting a blue green one on the top of a yellow one when the yellow will cut the blue out of the blue green and leave only green.

In working the subtractive process the three negatives are printed in coloured dyes the picture taken through the red filter being printed on gelatine dyed blue green the one taken through the green filter on gelatine dyed magenta and the one taken through the blue filter on gelatine that was dyed yellow. Now if the three are cemented together in register the resulting transparent colour picture will reproduce the colours of the original subject and will be a transparency which can be viewed in the hand or examined in front of an artificial light or projected in a lantern.

**Printing Methods—**Subtractive methods have naturally attracted the most attention for giving prints on paper.

The carbon process was used by du Hauron the negatives being printed upon carbon tissue containing a pigment of colour complementary to that of the filter. After development the three

negatives are transferred to temporary support and then re-exposed to a different support in accurate register. This process requires considerable skill.

The three images obtained by the use of a colour photograph can be transferred to a different support by the carbon process. This involves the use of carbon tissue containing a pigment of colour complementary to that of the filter.

The three images obtained by the use of a colour photograph can be transferred to a different support by the carbon process. This involves the use of carbon tissue containing a pigment of colour complementary to that of the filter.

This involves the use of carbon tissue containing a pigment of colour complementary to that of the filter. The three images obtained by the use of a colour photograph can be transferred to a different support by the carbon process. This involves the use of carbon tissue containing a pigment of colour complementary to that of the filter.

In addition to the processes colour images have been made by using for dyeing the mordanting power of chemical compounds and especially the ferrocyanides of the metal. The ferrocyanides of uranium, copper, vanadium and silver and the iodide or sulphocyanide of silver mordant blue dyes very strongly. From the negatives silver images are therefore prepared and transferred into these compounds. The blue image is commonly composed of iron ferrocyanide itself the being a very suitable shade of blue for colour work. Yellow and red images are obtained by mordanting basic dye such as auramine and safranine on to transparent deposits of metallic compounds. The three images are then superposed as usual.

In one group of processes the dye images themselves are transferred from the printing plates which are formed of colourless reliefs these being stained up and then placed in contact with gelatine so that the dye migrates and forms an image in the gelatine. Such processes are known as imbibition processes. The transfer plates may be made in several ways thus bichromated gelatine on film may be exposed through the back and developed with hot water or a silver image produced by exposure through the back of an ordinary emulsion coated film may be caused to harden the gelatine either during development or once some developers harden the gelatine contiguous to the image or by treatment with a bath similar to that used in the ozobrome process already referred to. After treatment a relief can be obtained by washing off the unhardened gelatine with hot water and after removal of the silver a colourless relief is obtained. In a process known as the Pinatype process bichromated gelatine is exposed under a positive and is then treated with dye which penetrates only the soft gelatine the hard gelatine remaining uncoloured. This dye can then be transferred by imbibition to a layer of soft gelatine coated on paper and the three images can be transferred in turn to produce a colour picture.

In a modification of this used in motion picture colour photography the local hardening is produced not by the light exposure of a bichromated surface but by the formation of a silver image and its treatment with a bleach bath which hardens the gelatine in contact with the developed silver.

There are numerous modifications of these printing processes all of which can be employed with more or less success but all of which require a considerable amount of skill if really good results are to be obtained.

The largest field for the subtractive process of colour photography is in connection with the use of the printing press. The three negatives are used for the production of printing plates usually by the half-tone process and prints from the three plates, frequently with a fourth black plate added are superimposed, the plates being printed in red, blue, and yellow inks which are approximately complementary to the colour of the taking filters. This three or four colour half-tone process is very widely used for the preparation of illustrations and is by far the greatest application of colour photography. (See PHOTO-ENGRAVING)

**Screen Plate Processes**—In the book *Duco du H. u. on u* ed in the of the e e p r e s s w r i t h i n e e l e c t r o n o f e l e c t r o n a r r a n i k r o n t e s c r e e n p l a t e p r o c e s s H. L. L. e d t h e u e o f t h e p l a t e o n m e t h o d s o f t h e f i l m — r e d g r e e n a n d b l u e — i n t h e e l e c t r o n c o l o u r e d o p p o s e t h e s e a n d p h o t o r a p h t h r o u g h t h e f i l m s

A method of the method is used by J. Joly or Dublin and J. W. McDonough or Chicago in the colour element on a plate which is coated during exposure to a colourant with a special electron plate after development of the negative is positive in silver in the usual way and viewed in contact with a special viewing screen in which the colours appear to be those required by the eye. This method is employed in the final process much used in recent years particularly for work in the studio and in the field for making colour originals from which three colour printing plates can be made. Any number of duplicate colour transparencies can be made from the original negative.

In 1907, Messrs Lumiere and Co. of Lyons brought out their Autochrome plates in which they utilized an irregular screen composed of coloured grain. Glass plates are coated with an adhesive medium over which there is spread a mixture of starch grains of microscopic fineness stained violet green and orange the interstices being filled in with fine carbon powder to form a tricolour screen dark by reflected and of a pearly pearly appearance by transmitted light. This is varnished and coated with a thin panchromatic emulsion of gelatin silver bromide. The plates are exposed in the camera from the back through the tricolour films a special compensating orange yellow screen being used also before or behind the lens. They are then developed as usual producing a negative coloured image in the complementary colours which is then reversed so as to produce a positive coloured image showing the picture in its proper colours. The results thus obtained are remarkably good and practically solve the problem of direct colour photography in a simple and fairly inexpensive manner the results being of course confined to transparencies.

In recent years other screen plate processes of this type have been introduced. They include the Agfacolor plates and film in which stained resin grains are used instead of the starch grains of the Autochrome process. In Dufaycolor the emulsion is coated on a screen ruled on the glass or film support to give a regular pattern.

Screen plates are conveniently studied under the following heads —

- I Method of production of the screen
- II Examination of the screen as a whole
- III Examination of the filter units
- IV Examination of the emulsion
- V Adjustment of the compensator and emulsion to the filters

I The screen may be either regular or irregular. The methods of production may be classified as follows

- (1) Ruled lines. Method used by Joly and McDonough
- (2) Dusting on methods. Employed to produce irregular screens in the Autochrome Agfa and Lignose processes
- (3) Printing by means of bichromated colloids. These are used in the Warner Powrie Finlay and Duplex processes
- (4) Various methods of section cutting. The best known example is the Krayn screen introduced in Germany in 1907 and taken off the market shortly afterwards

(5) The use of mechanical printing or a combination of mechanical printing and dyeing. The Omnicolor and the Lumiere regular screens neither of which was marketed commercially were made in this way as is the Dufaycolor screen now in use.

(6) Other processes. A variety of patents have been taken out for experimental screens which must be classed under this heading.

II The screen as a whole when examined should appear to be of a neutral shade. This is known as the first black condition. The adjustment is obtained by alteration of the area of the units as far as possible rather than by adjustment of the depth of

colour. The total visual absorption should be as low as possible.

III The separate filter units should have the purest possible colour spectrum without overlap in the spectrum. The best possible compromise is for a red filter transmitting from  $\lambda$  590 upwards a center from  $\lambda$  590-490 and a blue filter from  $\lambda$  500 down to the violet. The size of the screen units is determined by their invisibility. In order to get bright colours however it is necessary that they should not be too small since otherwise the emulsion will not have sufficient resolving power and the images behind the units will overlap. For regular screens the units should not be larger than  $\frac{1}{30}$  nor smaller than  $\frac{1}{50}$  of an inch. For irregular screens it is necessary that the units should not be larger than one third the dimension of regular screens since the average unit will tend to be a clump of about 10 grains that is having approximately three times the diameter of the single unit.

IV The emulsion should be sensitive to the whole visible spectrum and of a resolving power depending on the size of the units. In the case of the small units of irregular grains its resolving power must necessarily be high so that the emulsion must be low and fine grained. It must also be coated in very close contact with the screen since otherwise the scattering of the light in the intervening space will affect the colour.

V The emulsion should be so sensitized that the effects produced under the red and green filters are equal if possible. The compensating filter used on the lens can then be adjusted to the emulsion and to the filter units so that the second black condition is fulfilled that is a scale of greys is rendered as grey after exposure development and reversal.

The effective speed of a screen plate is governed by three factors (1) The sensitiveness of the emulsion (2) the multiplying factor of the screen (3) the multiplying factor of the compensator. The effective speed of the screen plates on the market is lower than that of normal negative materials although at the present time they are fast enough to enable snapshots to be made.

Owing to the very thin emulsion necessary to give sufficient resolving power the latitude of the process is small and in subjects with wide contrasts the shadows may be underexposed while the highlights lose colour owing to overexposure and the consequent irradiation. Except with very flat subjects there is practically no latitude in the exposure given in the camera the results depending entirely upon the accuracy with which the exposure is determined.

One drawback to screen plates lies in the fact that they must be viewed as transparencies either by projection or in a simple viewing device. The magnification under which they can be viewed is limited by the fact that the image is broken up into small units.

A process which is in some respects analogous to the screen plate process is one invented by R. Berthon in which film is embossed on the back with minute lenses. A tricolour diaphragm is then placed at the lens of the camera and the film is exposed through the back so that the lenses form images of the coloured filters on the emulsion.

After exposure and processing by reversal the film is projected with a multi colour diaphragm attached to the lens of the projector and the colours of the original object are thus reconstituted on the screen. This process is used entirely in motion picture work.

**Bleach out Processes**—Since many dyes are destroyed by the action of light and since Grotthus and Draper showed that dyes are bleached by light of the colour which they absorb it is clear that a printing process can be produced by mixing three colour dyes which are sensitive to light. Thus if we make a mixture of auramine—which is bleached by blue light erythrosine—which is bleached by green light and methylene blue—which is bleached by red light and coat this mixture in a layer of paper we shall get a black surface. Now if this be printed under a coloured original the dyes which absorb the colours will bleach and a coloured reproduction will be obtained, the accuracy of which will depend upon the correct adjustment of the conditions. The most important of these conditions is the relative sensitiveness of the different dyes and the choice of dyes which have the correct ab

## APPARATUS

Photographic apparatus may conveniently be discussed under the following heads —(1) Cameras and their construction (2) Enlargers (3) Stand (4) Lenses (5) Light Filters (6) Shutters (7) Exposure Meters (8) Developing and Printing apparatus and finally (9) Studio and Darkroom appliances. In the case of Cameras and Lenses further subdivisions of topic will be needed. Owing to the multiplicity of models it will be necessary to curtail greatly the space devoted in former editions to historical development in order to deal at all adequately with features of construction in relation more particularly to modern types. Even here severe compression has rendered unavoidable the omission of many details of mechanical and optical interest. For

## CAMERAS AND ENLARGERS

The original aim of the pioneer in Photography was to fix the image in the camera obscura (16) and Wedgwood and other early workers chiefly employed that cumbersome apparatus in the experiment.

**Historical**—Between 17 and 189 Nicéphore Niépce Fox Talbot and De la Rue used smaller box camera and it is on record that the expanding bellows box principle was applied to some of the first camera made in France for the production of Daguerreotypes. In England this construction was not adopted until much later the usual practice being to make the camera in the form of two open boxes one sliding within the other in order to provide the adjustment necessary for focussing. The two parts were supported on a rigid baseboard the adjustment being fixed by a screw. A portable stereoscopic camera with parallel bellows

FIG 18 —FOLDING KODAK

designed by J Atkinson in 1857 was followed in 1858 by C T H Kinnear's lighter pattern with conical bellows for general work. Thenceforward the manufacture of British cameras progressed rapidly in the hands of P Meagher, G Hare W Watson and other competent makers. One of the later models of the last named, known as the Premier, having survived to the present day as a typical square form pattern for technical work.

Information on early cameras will be found in the photographic journals in C. Fabre's *Traité encyclopédique de photographie*, Vol. 1 and in J. M. Eder's *Ausführliches Handbuch der Photo*

Workable device for the camera or for portable camera use is the roll film camera. The roll film camera is a camera in which the sensitive plate or film is in the form of a continuous strip of material. The strip is wound on a spool and is unrolled as the camera is used. The strip is then re-wound on the spool. The roll film camera is a portable camera and is used for taking pictures in the field. The roll film camera is a camera in which the sensitive plate or film is in the form of a continuous strip of material. The strip is wound on a spool and is unrolled as the camera is used. The strip is then re-wound on the spool. The roll film camera is a portable camera and is used for taking pictures in the field.

Roll film camera produced in the form of Kodak box form and collapsible the latter culminated in a folding camera which has been widely imitated in the country and on the Continent. To day the output of roll film cameras greatly exceeds that of any other type but several other forms continue in request. Continuous roll film camera cut film camera film pack (q.v.) sheaths have increased the popularity of the extruded portable hand or stand cameras such as the Sphero of Newman and Curd and the more substantial line of Jan. Sinclair and Co. Stereoscopic cameras of exquisite workmanship and extreme precision such as those of J. Richard Voigtlander and Leitz have many users. The Reflex both ordinary and folding is a favourite for nature study and other special work and a considerable camera is based on the original Goerz Anschütz pattern are very nicely employed for Press photography.

The outstanding feature of latter-day camera manufacture is the preponderance of instruments to take plate and films of the smaller sizes including the taking 35 mm. cinema film. With modern emulsion negatives made with vest pocket cameras will yield excellent enlargements. Naturally this facility appeals to the average amateur and also in a measure to professionals. In fact to day the enlarger is complementary to the camera to such an extent that in any modern photographic exhibition the proportion of contact prints from negatives taken directly in cameras is conspicuously small.

**Construction.**—In some portable cameras the application of the fixed focus principle renders any focussing adjustment superfluous but otherwise the latter is a primary constructional requirement. Today most focussing is accomplished automatically. In the earlier cameras the extension—almost invariably by means of leather bellows pleated accordion wise—was regulated by an endless screw operated from the front or back. The method is occasionally employed in big copying apparatus but has been largely supplanted by a rack and pinion action on the back of the camera if the bellows are parallel and on the front where conical bellows are racked out from the back. The front sometimes the back also is kept rigid by struts or other supports affixed to the baseboard and the lens usually mounted on a sliding panel can be lowered or raised to modify the amount of foreground included. Convergence of vertical lines caused by tilting the camera can be corrected by a swinging back or front which enables the base of the sensitive plate to be kept horizontal and its sides vertical irrespectively of the tilt. A swing back or a side swing is also occasionally useful for bringing into focus a foreground or a near object on one side or the other of the subject without stopping down. Focussing is ordinarily carried out with stand cameras by viewing the image formed by the lens on the piece of finely ground glass constituting the *focussing screen* a cloth being thrown over the camera to exclude extraneous light. In some cameras notably those of the reflex type a focussing chamber enables the focussing cloth to be dispensed with and in most hand cameras the focussing screen is replaced by the finder (q.v.). For certain scientific purposes it is preferable to focus on a piece of plain glass with a focussing magnifier which thus virtually becomes the eyepiece of a telescopic system but 'aerial focussing' as it is called is unsuited to ordinary photography in which composition of the subject as a whole must be studied.

The focussing screen, and later the dark slide or other receptacle for the sensitive plate or film is now usually held at the back of stand cameras in a frame which is reversible for pictures

taken with the plate lenswise or upside

Dark slide to hold sensitive plates or cut films in sheaths are made to interchange with the focussing screen the sensitive surface of the plate or film being in accurate register with the rounded surface of the screen. Slides are commonly made to hold two or three back to back with a metal partition to prevent repetition of light. There are two patterns book form hinged to open like a book and solid the latter generally known as plate holder. With some hand cameras single metal slides are supplied. In all slides light is temporarily excluded from the front of the plate or film by a sliding or roller shutter which is removed or opened of course for exposure.

In the case of *studio cameras* (q.v.) a repeating slide enables two plates to be quickly exposed in succession without removing the slide itself. In field cameras other methods are adopted both to facilitate speedy consecutive exposures and to permit the carriage of a number of plates or cut films in less space than is possible with separate slides or plate holders. Some patterns of changing box are very compact and convenient. The usual construction is in the form of a box with a sliding door at the back to the open top of which a small bag of light tight material is affixed. The sliding door at the back having been removed the plates or cut films in sheaths are packed into the box and a spring at the back ensures constant and even pressure upon all the sheaths in the pack with the result that the front plate or film is always in register with the focussing screen. In the front of the box there is as in the case of the ordinary dark slide a shutter which is withdrawn for and replaced after exposure. The front plate after exposure is either lifted or levered up into the bag at the top of the box and transferred to the back.

Slides plate holders and changing boxes have largely been superseded for amateur use by roll film cameras based on the Eastman Kodak system. In the earlier applications of the latter the roll of film was carried on a spool in a separate holder with removable back and shuttered front which thus became a sort of changing box. But the roll holder is now incorporated in the camera itself with appreciable increase of portability and convenience and no loss of efficiency. The film itself in a long strip sufficient for several exposures is backed by a longer strip of black paper on which at suitable intervals the number of the exposure is boldly stamped. The excess of black paper at either end of the film provides a safety covering during the process of loading the spool into the camera and thus enables the latter operation to be performed in daylight. In practice the lens being normally capped by a central shutter the back of the camera is removed and the spool inserted at one side of the roll holding arrangement. At the other side an empty slotted spool should be in position. The seal of the full spool having been broken a portion of the safety covering is unwound and threaded into the slot of the empty spool. The back which is provided with a small red window is now replaced. By means of a winder more of the black paper is wound off until the number (1) appears in the little red window. The section of film for the first picture is now in position.

An alternative method of daylight loading is provided by the film pack system whereby cut films are interleaved with pieces of black paper provided with numbered tags the whole pack being backed by a sheet of metal provided with springs. By pulling out one of the tags a sensitive film is brought into position for exposure the preceding film having been simultaneously displaced. Much progress has been made in packing film methods of loading and transfer with the result that backings may be entirely eliminated or specially treated to protect against unusual exposure such as X rays. Nearly all loading to day is integral with the camera and actuated by automatic or semi automatic means.

With all hand cameras some form of *finder* is required. The earliest finder was a second camera and this idea survives in twin lens and binocular cameras although a combined 'single' unit has been developed. It is an attachment either of the direct vision kind with or without a lens or lenses or in the form of an angled reflector in which an image produced by a miniature lens and which represents on a small scale the image transmitted by the lens in actual use is viewed by the photographer.

## TYPES OF PHOTOGRAPHIC CAMERA

FIG 19—ENSIGN STUDIO CAMERA AND STAND

noisily by a bulb. Prior to recent changes which have greatly modified the appearance of both the main difference between a studio and a field camera lay in the back arrangement.

*Field cameras* are of many sorts and sizes and include several classes to which special attention is being given. But the description field may be said to belong properly to the kind of camera used in the open and on a stand for general work which is not ordinarily attempted in the studio such as large groups and *genre* studies in natural surroundings as well as architecture and landscapes. Such a camera must be reasonably portable if plates of a fair size have to be exposed and it should possess in addition to a swing back (or front) and a rising and falling front an extension sufficiently variable to enable lenses of relatively long or short focus to be used. Thus a half plate camera the lens normally employed with which would probably have a focal length of 8 in. should have a full extension of not less than 16 in. and it should be possible to rack it in to take wide angle lenses with a focal length of not more than 4 in. As it is essential that a field camera should be quite rigid when fully extended the design of an instrument possessing this qualification in addition to that of portability presents some difficulties.

The square form camera equipped with parallel bellows remains a favourite with many for field work, owing to its rigidity and adaptability to all classes of subjects and all types of lens. Only moderate portability however is possible with this model and a rather substantial tripod is needed to support it at all satisfactorily. For sizes above half plate accordingly a lighter form of camera with conical bellows is frequently preferred and provided that the design is good and the material and workmanship all they should be, a field camera on these lines will meet all requirements. Formerly only a well made conical bellows camera would carry a variable telephoto lens without risk of vibration today many designs are offered which eliminate or diminish this hazard. Some conical bellows models have base boards in which a circle has been cut out and a metal ring inserted thus constituting a tripod head to which ordinary tripod legs can be attached.

FIG 20—NEWMAN AND GUARDIA BABY SIZE YBIL

In the *Sybil* (fig. 20) of the firm named Newman and Guardia is secured by a neat and effective arrangement of extension. Another representative model of this type is the *Sybil* which while less compact than the *Sybil* is sufficiently portable and only a little less efficient than the *quadrant*. The standard of the Houghton Butcher Co. is remarkable for the length of its extension, the latitude of its rising falling and swinging front movement and the ingenious provision made for the use of very short focus lenses.

*Collapsible hand cameras* are largely used for Press photography. They form a type apart of which the Goerz Anschutz was the pioneer model. A typical modern camera of this class is the Ross Panros (fig. 21) which is not only extremely convenient for hand work but can be so effectively used on a stand that it was adopted by the Royal Engineer for the field equipment of their Printing Company by whom it was extensively employed in the World War. Cameras of this kind are fitted with focal plane shutters (see p. 55) and very rapid lenses  $f/4.5$  being a usual aperture. In the *Erno* made by the Zeiss Ikon Co. an *Erno* anastigmat working at  $f/1.8$  has been fitted with which instantaneous photographs can be secured in a theatre with ordinary stage lighting.

*Magazine cameras* in which a number of plates or films are packed and brought forward successively for exposure somewhat on the principle of the changing box are now comparatively seldom used. Unless of the simplest construction in which case they are bulky the changing mechanism is apt to give trouble.

FIG 21—ROSS PANROS CAMERA

*Binocular and twin lens cameras* represent an endeavour to provide the operator with a view of the object up to and including the moment of exposure. They are literally as their name implies combinations of two separate cameras and two separate lenses, the focussing adjustments being correlated so that one half of the combination can be used for focussing the other for exposing the plate. In the form of an inverted field glass the focussing screen and the plate taking the place of the two eye pieces, binocular hand cameras are still to be met with but the twin lens which in its later forms was an early reflex has been practically superseded by the single-lens reflex.

Modern *reflex cameras* form a class apart in connection with which much ingenuity of invention has been displayed and many patents have been taken out. The principle is explained in the accompanying diagram (fig. 22) but as in practice the reflex is usually held in the hand, it is now fitted with a collapsible vertical hood which enables the operator to look down through it on to the focussing screen. A second mirror can, if desired, be fitted in

FIG. 25—ALDIS ENSIGN ENLARGER

Cinematography is dealt with under MOTION PICTURES (see especially MOTION PICTURE TECHNOLOGY by C. F. K. Mees). Aerial photography is treated under AERONAUTICS and AVIATION, also under SLIDING. X-ray photography is discussed under X-RAYS, X-RAYS AND CRYSTAL STRUCTURE and related subjects.

**Enlargers**—The old method of enlarging by direct photography with a short focus lens and an ordinary camera of long extension has for a number of years been largely discarded in favour of the employment of apparatus resembling the ordinary optical lantern. In the modern enlarger (fig. 25) a negative or a transparency takes the place of the lantern slide, the screen being represented by an easel to which a piece of bromide paper or a sensitive plate is, after focussing, affixed. A powerful beam of artificial light is passed, with the help of a condenser, through the negative or transparency and the enlarging lens with the result that an image is projected varying in enlargement according to the distances between the negative and the lens and between the lens and the sensitive surface of the paper or plate. The illuminant may be either electric light or gas, but the former is now generally preferred, partly because it facilitates the construction of vertical enlargers which have some advantages over the horizontal form. A number of automatic enlargers have been designed.

Enlarging can also be carried out without condensers by collecting the rays of an illuminant in a reflector of ellipsoid form from which a parallel beam of sufficient size is passed through the negative. The latter may be held in the dark slide of an ordinary camera which, with its lens, is thus made to take the place of the front portion of an ordinary enlarging lantern.

The *Photostat*, an American invention introduced about 1907

and since greatly developed, is a combined camera and stand with fully automatic mechanism for the reproduction of various kinds of official and commercial documents by unskilled operators in any ordinary well-lighted office. Any scale of enlargement or reduction can be adopted, and copies developed and fixed in not many seconds. A very rapid colour sensitive paper is used, rendering the system valuable for copying engineers' and architects' plans, etc. See *BJA* for 1938 p. 180 (*See LITHOGRAPHY*).

**Stands**—For studio cameras (*qv*) as previously noted, stands of substantial pillar construction are usually provided. With copying and other large cameras the stand is more often in the form of a table, but also provided with raising, lowering, and tilting movements. For enlarging purposes the stand and easel are sometimes combined, runners enabling the conjugate distances to be readily varied. But for all general photographic purposes the tripod form of stand is the most practical, and almost innumerable patterns in wood and metal have been evolved. For very small cameras tripods with telescoping legs of an aluminium alloy and a top of harder metal meet the demand for extreme portability, but for serious work a substantial wooden pattern is greatly to be preferred. The legs should telescope to make them not only more portable but also adjustable to uneven ground. For special work a revolving or tilting head may be desirable, and in some patterns provision is made for increasing the height of the camera from the ground by means of a second raised head. An important new device is a tripod with a universal ball and socket which compensates for weight and tilt of camera.

For the incidental snapshot work to supplement the ordinary tripod, a unipod is employed as a support for a tele-

photo or other he v' en af a' t' a' m' r' which of final  
cor ru tion

### PHOTOGRAPHIC LENSES

**Historical**—The first portrait of photographic objective was an adaptation of W. H. Wollstone's deep perspective lens which was adapted by him to the camera of the first. This was adapted by C. Chevalier for use about 1839 by D. Niépce.

FIG 26 — HEIDOSCOPE STEREO REFLEX CAMERA

but was not corrected for chemical focus. The first photographic lens corrected for chromatic aberration (see later under *Construction*) was a doublet made about 1840 by Andrew Ross for H. Collen and consisting of two achromatic compounds one at each end of a tube (fig. 27).<sup>1</sup> Many single lenses of good performance were produced by the early photographic opticians T. Grubb's Aplanatic (1857) and J. H. Dallmeyer's Wide Angle Landscape (1865), Rapid Landscape (1884) and Rectilinear Landscape (1888) being notable examples.

In 1841 a remarkable advance was achieved by Voigtlander's introduction of a rapid portrait lens designed by Professor Petzval of Vienna (fig. 28) to whom is due the historic condition that the sum of the focal powers of the individual lenses in a photographic combination multiplied by the reciprocals of their respective refractive indices should be equal to zero or  $\sum \frac{1}{\mu f} = 0$ .

This pioneer portrait lens consisted of two dissimilar achromatic combinations widely separated, the front element being a plano

<sup>1</sup>In the diagrams of lenses which follow a uniform system of indicating the nature of the glass employed by means of the shading has been adopted.

- Flint glass is indicated thus — 
- Crown glass of low refractive power thus — 
- Crown glass of high refractive power thus — 
- (These two are used indiscriminately in lenses made before the introduction of the new Jena glass.)
- Extra light flint glass thus — 
- In most cases the front of the lens is on the right.

FIG 27 — FIRST ENGLISH PORTRAIT LENS

convex composed of a biconvex crown cemented to a plano concave flint while the back element was a double convex composed of a biconvex crown separated by an air space from a concave convex flint. The form was notably improved by J. H. Dallmeyer who in 1866 reconstructed the back combination by substituting a meniscus crown for the biconvex element and a shallow concave convex positive meniscus for the negative meniscus reversing the position and introducing an air space.

In 1861 J. H. Dallmeyer produced a triplet very fully achromatised non-distorting and giving excellent definition but since obsolete on account of its bulk and lowness.

Between 1841 and 1866 a number of doublets were brought forward by British and Continental opticians with the object of increasing rapidly and eliminating distortion and towards the end of this period a simple and efficient type of rectilinears, symmetrical and aplanatic had become established. In the manufacture of these a high degree of excellence was attained particularly by Dallmeyer and Ross in England and by Steinheil in Germany (fig. 29). Wide angle symmetrical doublets with greatly

deepened curves appeared about the same time some exhibiting remarkable qualities of definition combined with covering power. Dallmeyer's Rapid Rectilinear f/8 (1861) set what remained

as the standard for photographic lenses for ordinary purposes until the perfection of the anastigmat. Among slower combinations the Portable Symmetrical of Ross was remarkable for its flatness of field and a compactness which enabled a number of lenses of widely different foci to be fitted into the same flange.

The issue in 1886 by Schott and Genossen of the Jena glasses formulated by Professor Abbe placed in the hands of photographic opticians a means of eliminating astigmatism by setting high refractivity with low dispersion against low refractivity with high dispersion. Some of the early Jena glasses were unstable and progress in construction was at first slow. In 1888 Dr. Schroeder worked out for Ross an anastigmat afterwards known as the Concentric Lens but the first thoroughly successful objective made with Jena glasses was that designed in 1889 by Dr. Paul Rudolph of the Zeiss firm and classed as Series II f/6.3.

The details of construction are to be found in the *Eder Jahrbuch* for 1891 and 1893. This excellent lens was followed by several other anastigmatic singles and doublets a new line being struck out by the symmetrical cemented doublet of C. P. Goerz known as the Dagor which has since been widely imitated. Almost simultaneously the single Protars of C. Zeiss came to be combined in doublet form. These improvements soon showed themselves to be as excellent in practice as they were in theory.

In 1895 Taylor, Taylor and Hobson produced a remarkable and entirely novel anastigmat designed by H. D. Taylor and known as the Cooke lens (fig. 30). It consists of three single lenses: a biconvex crown in front, a very flat biconvex crown behind with a biconcave of light flint in between and close behind the front crown. Also in 1895 H. L. Aldis calculated for Dallmeyer a new convertible anastigmat consisting of two dissimilar compounds thus giving a choice of three foci. The "Stigmat," as it is called, is still issued but in a non-convertible form. In 1902 H. L. Aldis produced at the new works of Aldis Brothers at Birmingham a much simpler anastigmat composed of a

In 1891 T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris simultaneously worked out telephoto graphic combinations consisting of positive and negative elements which produced magnification according to the extension employed.

## CONSTRUCTION OF PHOTOGRAPHIC LENSES

The construction of technically good photographic lenses of which some indication has been given in the preceding historical summary depends largely upon the elimination of certain defects of which the principal are (1) Spherical aberration (2) Coma (3) Astigmatism (4) Curvature of field (5) Distortion and (6) Chromatic aberration. Spherical aberration is due to the fact that a spherical surface does not bend or focus light to one exact point in other words the rays passing through the edge of such a surface do not focus to the same point as those passing through the centre. It can be partly corrected in a single lens by the use of a diaphragm and in combinations by varying the curves of the component lenses. Coma and astigmatism are functions of spherical aberration the first being a blur due to lateral spherical aberration of oblique rays. It is partly eliminated by the diaphragm. Astigmatism manifests itself in inability to focus accurately at the same time both vertical and horizontal lines.

FIG 33 —ZEISS S TESSAR

It is partially caused by the use of a material which can be badly contaminated by the action of the atmosphere. The cause of our Cavalier's defect is a lens with a spherical aberration. The rays of the rays here. Distortion is of two kinds. One is a spherical aberration in the former sense. The other is a spherical aberration with the con- siderable spherical aberration employed in the front of the lens. The spherical aberration is— if photographed with a lens which is out of focus and with the diaphragm shut. It is a spherical aberration in symmetrical doublets since the spherical aberration of one component compensates the spherical aberration of the other. Chromatic aberration is caused by the dispersion of the light passing through the lens and is due to the fact that the different coloured rays come to a focus at different distances from the focal point according to their wave length. It is corrected by compensating lenses of different refractive powers (see Optics). In the general construction of photographic lenses the defects which were enumerated above to be corrected with a number of others are neutralized by regulating the curves of the different positive and negative component lenses, the relative and dispersive indices of the glasses used and the distances of the refracting surfaces in this manner making the objective truly stigmatic or focussing to a point.

## PROBLEMS OF FOCUS

The fact that *depth of focus* is conditioned not only by aperture but also by focal length has an important bearing upon the construction of very large aperture lenses. It is obviously of small use to build a cumbersome and costly lens with a focal length of, say 12 in. and an aperture of say  $f/3$  for ordinary work, in which the lens would almost invariably need to be stopped at any rate to  $f/8$  to secure reasonable 'depth'. But, with the extended use of diminutive cameras carrying very short focus lenses, the demand for very wide apertures has grown enormously, and

The term *focus* explained in the general article on LENSES (*q. v.*) but it may be pointed out here that the equivalent focus of a photographic lens must be measured from the nodal point of emergence which is sometimes in front of the front component. The historical genesis of the principal forms of photographic lenses having already been sketched their actual construction apart from the optical considerations dealt with in the general article on LENSES (*q. v.*) may now be glanced at. The single lens seldom produced commercially to day except as a component of a doublet or triplet or in connection with the cheaper amateur outfits. In the latter case it is a simple achromatic meniscus composed of a biconvex crown cemented to a biconcave flint. The single components of the better types of Rapid Rectilinear are constructed in a somewhat different manner. Anastigmat singles such as those used to make up the combinations of the Zeiss Protar the Ross Combinable the Steinheil Orthostigmat the Watson Holostigmat and the Voigtlander Colinear are usually triple compounds of peculiar Jena or Chance glasses. In addition to the symmetrical doublets formed by the combination of two simple singlets there are a number of variously composed asymmetrical doublets some with cemented others with air spaced components are also notable combinations which although assembled in two cells are more or less frankly triplets. The Zeiss Tessars which are entirely asymmetrical consist of three separate components that in front being a cemented lens the other two uncemented the intermediate one being a double concave. In the construction of most modern doublets and triplets air spaces play an important part. (See LENSES.) Multiple combinations such as the Beck Isostigmat in some forms of which five separate lenses are sometimes used are uncommon.

One interesting development has been by Zeiss in his use of converging achromatic eyepieces (consisting of two self contained groups of lenses) for increasing marginal thickness of lens.

Apart from or in connection with their standard models some lens makers have designed *supplementary lenses* to lengthen or shorten the focus of ordinary objectives. In their simplest form such lenses are either long focus negative or positive singlets which can be attached to the front of an ordinary objective with necessarily some disturbance of the original corrections. As far back as 1894 an advance in this direction was made by Taylor Taylor and Hobson in connection with their Cooke lens by producing a suitably corrected rear extension lens for increasing the focal length. More recently the same principle has been applied by the Zeiss firm to its Tessars in a series of Distars and Proxars the former lengthening the latter shortening the focal lengths of the original objectives.

The construction of telephoto combination is altogether distinct from that of ordinary photographic lenses. It is based on the fact that if a negative lens is placed behind a positive lens at a separation not less than the difference between their focal lengths (which constitutes the Galilean telescopic condition) and not more than the focal length of the positive element a photographic combination is formed the focal length of which increases as the separation is decreased. The back focus or distance from the back lens of the combination to the plate is not however correspondingly increased being dependent wholly on the focal length of the negative element a very important consideration as it enables considerable magnification of the image transmitted by an ordinary lens to be obtained with the same or less camera

extension. In 190 Capt Owen Wheeler introduced a system of combining tele negatives to produce compounds of extremely high focal lengths with which magnification up to X 30 is possible on a camera extension of only about 15 inches. A good feature of his system is that by making the rear lens of the combination one of relatively large diameter the covering power is greatly increased. Advantage was taken of this fact in a special complete tele lens recently used by the Royal Engineers in the World War which had a focal length of 30 in. and covered a 4 plate with a camera extension of 6 in. only.

Originally telephoto lenses were variable power ones—the separation of the elements could be altered at will to produce different magnifications with the same or with different tele negative. Also an ordinary photographic lens was generally used as the positive element. The arrangements were defective owing firstly to the disturbance of the corrections of the positive by a shifting negative element and secondly to the comparative slowness of the combination due to the fact that the aperture of any telephoto lens is the aperture of the positive multiplied by the magnification. Thus in the case of a variable power combination in which in order to obtain good definition the positive is stopped to say  $f/11$  the aperture at only 5 magnifications would be  $f/55$ .

Another drawback in the case of variable power combinations is their liability to internal reflections owing to the relatively long separation of the two elements. This is partially overcome by lining the lens tube with some non reflecting substance or material but a more effective plan is to fit a hood on the lens to cut out the extraneous light—a method often adopted with advantage in the case of ordinary objectives.

Variable power telephoto lenses are still used by specialists and extraordinary results are attainable with them. But in modern practice single focus combinations are much more common. In these the positive element is a cemented single lens of extremely wide aperture the defects of which are corrected in the negative element. The earliest examples of this form were the  $f/9$  Busch Bis Telar (1903) and the  $f/14$  Zeiss Magnar (1906) both since improved but these have been put into the shade by recent productions of Ross Dallmeyer Taylor Taylor and Hobson Zeiss and others. The principles and construction of the Telephoto Lens are discussed at length by H. W. Lee in the *Photographic Journal* for 1915 p. 39.

See Proc. Physical Soc. of London for 1935 Vol. 47 p. 50. Taylor and Lee for full summary of developments.

#### TYPES OF LENSES

Little need be added here to the note in the historical summary above on the subject of *Portrait Lenses*. It is a remarkable tribute to the genius of Petzval that the lines which he laid down in 1841 should be generally followed to day in the lenses commonly used for portraiture although naturally modifications and improvements have since been introduced by leading opticians. Ross Dallmeyer Taylor Taylor and Hobson in Great Britain and Voigtlander particularly on the Continent have produced many portrait lenses of great excellence and occasionally of gargantuan proportions. In some modern studios however the portrait lens of old days is yielding place to the anastigmat the wide aperture of which places it on a level with the Petzval construction in point of speed while its more perfect corrections and covering power render it specially serviceable in the matter of studio groups. In simple portraiture on the other hand extreme flatness of field is not always desirable a round fielded lens giving better modelling. Since good portraiture has little use for needle sharpness of definition artist photographers since the days of Mrs. Julia Cameron have sought in various ways to modify the critical rendering of objects in the same plane by a well corrected lens. One method of producing soft effects is by means of the diffusion created by partly unscrewing one lens of a combination. Latterly soft focus lenses have been produced by several opticians in which diffusion is secured by special computation the objective being duly corrected for flatness of field distortion and colour but yielding an attractively soft image of marked pictorial quality. A third soft focus method is the

The variety of the matter is not only a thing on which the maker for camera and work has to be considered but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention.

The variety of the matter is not only a thing on which the maker for camera and work has to be considered but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention.

Tesars makes them extremely popular their usefulness being enhanced where desired by supplementary lenses such as those mentioned above. Of triplets and asymmetrical doublets with components one or other of which is uncemented or a single glass a wide choice is available from the lists of Ross Dallmeyer Taylor Taylor and Hobson Wray and Aldis Brothers in Great Britain and of Zeiss Goerz Voiglander and others on the Continent the apertures ranging from  $f/1$  to  $f/6.3$  and the focal lengths from two to three inches up to as many feet.

In field work more especially in connection with architectural studies in confined spaces wide angle lenses are often necessary and much attention has been paid to this branch of lens construction both before and since the advent of the anastigmat. Of late years wide angle lenses with comparatively large full apertures—very useful for focusing in dark interiors—have been made by Taylor Taylor and Hobson who e VII B series superseding their previous Primoplanes open to  $f/6.5$  and at  $f/32$  give sharp definition throughout a field of  $100^\circ$ . The Wide Angle Aristostigmat of H Meyer the 4 in model of which covers a half plate at  $f/9$  is another successful lens of this type. For the particular purpose of Aerial surveying but also very useful for many other classes of work a new wide angle Ross Xpress embracing an angle of  $80^\circ$  and covering sharply from centre to margin at the very high aperture of  $f/4$  is a remarkable achievement the report of the National Physical Laboratory on this objective showing extraordinarily good corrections. Where an abnormally wide angle lens is needed the Goerz Hypergon which consists of two hemispherical lenses and has a frontal star diaphragm to equalize the light may be used to cover an angle of  $135^\circ$ .

Modern Telephoto lenses are as previously indicated very different from the early variable power type and much better adapted to latterday requirements. The magnification is small at the most  $\times 3$  but this is compensated by critical definition enabling enlargement to be carried out to the same extent as with negatives made with ordinary objectives. For the modern telephoto lens is corrected throughout as carefully as the best ordinary anastigmat being in fact itself an anastigmat fully achromatised free from curvature spherical aberration and coma and within its limits non distorting. Also as now made by half a dozen leading opticians it is rapid enough for all practical purposes even putting aside the latest 'ultra speed' models in which an aperture of  $f/3.5$  has been reached. The only drawbacks are bulk and somewhat restricted covering power but these do not constitute a high price to pay for a lens which will do very nearly all that the best ordinary lens will do at half the camera extension.

The variety of the matter is not only a thing on which the maker for camera and work has to be considered but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention.

The variety of the matter is not only a thing on which the maker for camera and work has to be considered but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention. In the case of the Ross Xpress, the maker has to pay attention to the fact that the lens is not only a thing on which the maker has to pay attention but also a thing to which the maker has to pay attention.

In colour photography a high order of colour correction is necessary and for three colour process and other colour work in which very great accuracy is essential it is desirable that the correction should be carried to the furthest practicable limit. This is done by means of special computation and glasses in *apo chromatic lenses* made by Ross Taylor Taylor and Hobson Zeiss and others. With a view to complete correction for colour a few quartz lenses have been made by British French and American opticians and further progress may be expected.

Lenses for cinematography receive mention in the article on MOTION PICTURES but passing allusion may be made to them here since those employed in cine cameras are photographic objectives pure and simple made in most cases to standard formulae. Some extraordinary results have been attained in the tiny lenses the Dallmeyer Dalmac having been adapted to cinematography in the 16 mm sub standard size in a variety of models one of which has a focal length of 1 in only with an aperture of  $f/1.5$ . A number of tele cine lenses are also available.

Very short focus photographic lenses are also used in *photo micrography* but are not so suitable for work at high powers as microscope objectives in conjunction with suitable eyepiece.

An unusual short focus lens of especial interest commercially is that employed in the (reflex) automatic film camera used for photographing meters in the telephone exchanges etc.

**Light Filters**—The principles on which orthochromatism and panchromatism are based having already been explained (page 814) the discussion of light filters for cutting out some rays and emphasizing others need not occupy much space although the subject when closely considered is of great scientific and technical interest. For the production of such filters various expedients have been tried including small glass tanks filled with suitably coloured solutions but in modern practice either specially coloured glasses or dyed gelatine strips cemented between glass squares or discs—preferably optical flats—are commonly employed. The making of gelatine strip for such filters demands some skill and patience a perfectly levelled glass plate being required on which to spread the dyed gelatine solution. The latter must of course be as clear as possible and stained a spectroscopically correct colour. A number of suitable dyes are available for making yellow and green filters for use with orthochromatic plates and blue (or violet) green and red filters for panchromatic plates when the latter are employed in three colour photography. Yellow filters are usually graded according to the extent to which they increase exposure. In addition to giving correct rendering of yellows and greens they are frequently of the greatest value in cutting out haze and enabling clouds and distant hills to be effectively reproduced.

Certain commercial filters such as the Ilford Gamma and the Imperial Impan, give accurate rendering of all colours when used with panchromatic plates from the same source of supply. The Impan, by attaining this result when used with

Commonly photographs are made in a laboratory produced by quacking the print on a squared grid. One known as a terrotype put in rows by mounted in cartons with black cloth or paper in order to retain the print.

For mounting prints a method of dry mounting by means of tissue which have been saturated with hellic is frequently adopted. To use dry prints laid on the mount in the dry mounting press in which heat is applied which cause the hellic to melt with the result that the print is cemented to the mount.

The business of photo finishing as it is termed in the United States or development and printing (D & P) as it is generally known in England is now a very considerable portion of the photographic industry many firms developing several million spool of amateur cartridge film every year. In the case of the large photo finisher the finishing plant collects film through the agency of a number of photographic dealers and returns the finished pictures to the dealers for distribution to the retail customer. Two important factors in the business are the short time in which it is necessary to get the work done often 4 hours or less and the great variation in the amount of business throughout the year the output in England for instance being ten times as much at the maximum in August as at the minimum in January. This variation in the amount of business is causing great attention to be paid to the provision of automatic machines in order to diminish to a minimum the amount of skilled labor required. When the rolls of film come in they are unwrapped in the dark room and numbered the number being either punched into the film or light printed on it. They are then held in clips which can be slipped over rods so that the films with a weighted clip at the end are immersed in deep tanks of developer. After a fixed time of development they are transferred to a rinse tank, fixed washed and again transferred to a drying cabinet.

Several forms of continuous machines have now been devised for developing the rolls of film. In these the rods carrying the films held in clips are moved continuously by a conveyor system through a system of tanks and finally through a drying cupboard.

The dried negatives go forward to a printing room where they are printed by contact upon developing paper the printers being adapted for rapid operation frequently by foot treadles and equipped with numbering devices. Automatic power driven printers have been designed and some printers automatically give the correct printing exposure in accordance with the density of the negative.

From the printers the paper goes to the developers. Most prints are developed in flat trays rinsed in water and fixed and are then washed in a rotating cage immersed in flowing water or in a series of flat trays through which water flows this being the form used particularly in England where it is known as a cascade washer. The washed prints are dried by being placed between two fabric belts which travel over a heated drum, these machines being known as belt driers' which deliver the prints dry within a few minutes.

Glossy prints are dried upon ferrotype plates in cupboards or with the most recent machines, upon polished metal drums to

Studio and Dark Room Appliances—*See Listing*

[illegible]

Dark Room — Merit to his old-fashioned dark room is due to the introduction of new designs of lanterns and other dark room equipment of orthodox and adapted to the needs and importance of the work in question. Of dark room lanterns and lanterns in particular there is an endless variety but no practical lantern in which either white light or such which while relatively bright is safe for the plates in the air but is used on a wall. The more recent lanterns, naturally but chiefly used for a short time a range of light. To be a lantern of different heights suitable for all kinds of plates and bromide paper lanterns attention has been given and in order to cope with the extreme brightness of modern lanterns lanterns have been devised by Whitten and others in which only reflected light is provided through the lantern. This precaution however is being rendered superfluous by the new methods of desensitizing. While these methods are not sufficiently effective to enable very rapid panchromatic plates to be developed by naked candlelight illumination is permissible after desensitizing which would formerly have been out of the question. The Ilford Co. has introduced a new safelight for use with desensitized panchromatic plates giving a pleasant green light by which development can be watched in comfort as well as in security. Many others have advanced useful equipment.

## PICTORIAL PHOTOGRAPHY

Portrait photography applied to the  
 social and domestic life of the nation but  
 the portrait of the individual is a matter  
 of the highest importance. The subjects with  
 which the photographer has to deal are those in which  
 the camera is used to record the human form as it  
 is in nature.

**The Nude**—For a portrait photographer the nude which  
 has been a subject for the painter for centuries is not  
 a new thing. It is a subject which is difficult to handle  
 because of the moral and artistic considerations which it  
 involves. The nude in photography is a subject which is  
 difficult to handle because of the moral and artistic  
 considerations which it involves. To present the nude by  
 photography simply as a study of the beauty of the human  
 form involves firstly the finding of a model of perfect  
 proportions and secondly extreme delicacy of  
 treatment to prevent degeneration into the recording of  
 mere nakedness. In modern times this class of work is  
 done in the studio of the professional photographers who  
 have greater facilities than the amateur but however  
 excellent their work may be technically it is usually quite  
 meaningless from the artistic point of view. The fine use  
 of the nude is to be found in the work of the Americans  
 especially those living in California where conditions  
 are exceptionally favourable and particularly in that of  
 Annie Brigman, Arthur Kales and Walter Collinge.

**Still Life**—In other directions photography has more scope.  
 Landscape, portraiture, domestic genre and still life all offer  
 opportunities to the camera worker with artistic education and  
 a trained eye. Still life in particular offers endless possibilities  
 for imaginative treatment by photography and some very beautiful  
 work of the kind has been done in the past by Baron de Meyer,  
 J. M. Whitehead and E. Seymour. It is a branch of photography  
 which the Japanese of the American Pacific coast have developed  
 upon lines of their own in recent times, grafting the American love  
 of startling eccentricities upon their own inborn sense of design.  
 In their aptitude for seeing a pattern or decorative effect in chance  
 combinations of the most commonplace kind they are unequalled.  
 The exploitation of effects of pattern of an eccentric or sensa-  
 tional nature if it did not actually originate in America certainly  
 reached its greatest development there some twenty years ago as  
 a method of self advertisement. Such it still remains.

The sounder development of modern pictorial photography  
 shows itself in a feeling for broader and simpler effects in a  
 stronger sense of pattern and in more attention to the form than  
 to the content of the picture. In other words the picture is no  
 longer expected to tell a story. As a graphic art photography has  
 certain disabilities for it cannot suppress facts and cannot omit  
 unwanted details at will. It can modify the presentation of the  
 facts but any suppression or alteration has to be done by sub-  
 sequent manipulations usually involving handwork upon the nega-  
 tive or print the legitimacy of which has been questioned.

## IMPROVED PRACTICE

**Fox Talbot**—The story of pictorial photography is largely  
 bound up with the progressive improvements in the materials with  
 which the photographer had to work. Fox Talbot's Calotype pro-  
 vided the first method of making pictures by the agency of light  
 and so added photography to the graphic arts. In the year 1833  
 he was at Lake Como endeavouring to make sketches with the aid  
 of the Camera Lucida but lacking the necessary skill of hand  
 sought to devise a means of recording automatically the view as  
 seen on the paper. After five or six years of experiment he was able  
 to demonstrate his discovery of the process which is the basis of  
 modern photography and two years later patented an improve-  
 ment of this under the name of Calotype. He himself was a  
 scientist rather than artist and it cannot be said that any of his  
 surviving photographs show an artistic impulse.

**D. O. Hill**—The first to put the new invention to a pictorial  
 use was a Scottish artist David Octavius Hill who having been  
 present at the meeting at which the disruption of the Scottish  
 Churches occurred conceived the idea of painting the historic

ere I involved the inclusion of some hundreds of figures. To  
 get such a drawing all these portraits would have meant a year  
 or two of labour and many might be dead before he could secure  
 their likenesses. His friend Sir David Brewster an eminent  
 chemist of the day told him of the newly invented photography  
 and at the same time introduced a young student of science Robert  
 Adamson of St. Andrews to attend to the technical manipulations.  
 For three years he worked at it and produced that series of por-  
 traits of Scottish notabilities that are amongst the greatest as  
 they are the earliest masterpieces of the photographic art. An  
 album containing fifty of the original prints of these was issued  
 in 1845 and is now in the possession of the R.P.S.<sup>1</sup>

In 1846 Hill returned to his painting, became secretary of the  
 Scottish Academy of Arts and died in 1870 so completely unknown  
 to fame as a photographer that not a single photographic paper  
 chronicled the event. Although references to his pictures occur  
 earlier (*Photographic Journal* 1854 vol. I p. 177 also 1864 vol.  
 IX p. 63) it was not until James Craig Annan began to interest  
 himself in Hill's work in the early nineties and published a series  
 of photogravure plates from the original paper negatives that he  
 really became known.

It was Hill's artistry and not his photography that achieved  
 greatness and it is well to bear this in mind when pictorial pho-  
 tography is twitted with not having done anything finer than  
 Hill did so many years ago. Such a reproach is no more just  
 than would be a similar one to the artists of today for not ex-  
 celling Titian and Raphael and Michelangelo. The *Girl in a  
 Flowered Gown* is an example of the work of Hill.

Little is known of any of Hill's contemporaries. Dr. White of  
 Aberdeen used photography for pictorial purposes and a collection  
 of his landscapes was shown at the R.P.S. in December 1922  
 (*Photo Journal* vol. LXIII p. 5) but the process was as yet  
 so imperfect that the long exposures and lack of colour sensitive-  
 ness of the negative material made photography chiefly a record-  
 ing medium for the scientist whence arose the tradition of sharp  
 uniform definition that distinguished its practice until the advent  
 of Mrs. Cameron in 1864.

**Albumen Paper and Collodion**—The introduction of  
 albumen paper in 1848 and of the collodion process of Scott  
 Archer in 1850 marked the next progression. Picture making was  
 a serious business in those days when the negatives were made  
 the full size of the finished print and had to be sensitized and de-  
 veloped in the field and when enlarging was as yet unknown.  
 Already in the winter of 1851 there was a small group in London  
 meeting regularly and by 1852 this had grown to such an extent  
 that it was felt the time was ripe for a photographic society.

## ROYAL PHOTOGRAPHIC SOCIETY

**The First Exhibition**—The holding of the first recorded ex-  
 hibition of photographers at the Gallery of the Society of Arts  
 in December of that year gave an additional impetus and in  
 January 1853 the Photographic Society of London came into  
 being. Other societies quickly followed and photographers multi-  
 plied. At the first meeting of the London Society one of the  
 Vice Presidents Sir William Newton R.A. a distinguished artist  
 read a paper in which he put forward several ideas that countered  
 the false standard of pictorialism accepted as the result of its  
 practice by those whose only qualifications were scientific.

The most admired features of a picture at that time we read  
 were sharp definition all over and a blank expanse of pure white  
 for the sky. Sir William made two suggestions that were a  
 direct attack upon the existing position. One was that the pic-  
 torialist should aim at a broad and general effect for which end it  
 was not necessary that the whole of the picture should be in sharp  
 focus. The other was that artificial means should be adopted to  
 obtain some suggestion of a sky either by local reduction or by  
 dabbing pigment on the back of the negative to simulate clouds.  
 These rather ruffled the photographers but the leaven worked  
 and by 1862 there was general agreement on the desirability of  
 adding skies to pictures since it was then impossible to secure  
 them on the same plate as the landscape. Already in 1856 a print

## Composures—F

For the first time in the history of photography, the art of composition was brought into the domain of the pictorial. The work of the early photographers was largely a record of the things they saw, and the composition was left to the chance of the camera. But as the art progressed, the photographer began to see the picture in his mind before he took the photograph. He began to select his subjects, to arrange them, and to compose them in a way that would make the most effective use of the camera's lens. This was the beginning of the pictorial movement, and it was a revolution in the art of photography.

His vanplu however, imitated Henry Peach Robinson on the point of employing his leisure time in attempting similar method of picture making. He had had some artistic training, he had carved one of the figures of the reredos of Ludlow church and one of his paintings was accepted by the Royal Academy before he was twenty-one. He started life in the book-elling business at Ludlow, Bromsgrove and London and whilst at Bromsgrove in 1861 learnt the daguerreotype process and subsequently Calotype and collodion in preparation for a photographic career. His early pictorial attempts are unknown with the exception of the small *Just with the poison bottle* (RPS collection) but in 1865 he produced a picture entitled *Fading away* from five negative which was first shown at the Crystal Palace and afterwards at Leeds. It excited a violent controversy on the possibility of exhibiting so painful a subject (a girl dying from consumption) to the public gaze. Robinson's fame was thenceforward established and for the next thirty years he was the leader of British photography. His style was essentially Victorian artistically sound but anecdotic. The principal idea was to make the picture tell a story. His three finest works *The Days work done* (1877), *Dawn and Sunset* (1885) and *Carolling* (1887) are now preserved in the RPS collection. The two former are magnificent examples of albumen printing measuring 30 x 1 inches.

**Further Inventions**—In the late fifties Pouncy's Gum Bichromate process and Poitevin's Carbon process were added to the existing printing media. The former received little attention but Carbon was developed commercially by Swan and the Autotype Co. and was taken up slowly by photographers.

**A Notable Amateur**—The advent of Mrs. Julia Margaret Cameron in 1864 marks the next stage in pictorial development. The casual gift of a camera and lens by her daughter led her to take up photography at the age of fifty with all the volcanic energy of her temperament. She was one of a highly gifted family and had been closely associated with Watts and the painters of the Pre-Raphaelite school so that she brought an unconventional mind to the exercise of the new art. Her lens was of an uncorrected type and without waiting to learn the correct adjustments she proceeded to use it in the manner that suited herself. She broke through all conventions and produced a series of heads distinguished by great breadth of modelling, indeed in the case of the Carlyle and Herschell by a violence of treatment that rather horrified the photographers of her time. The reviews of the exhibitions made some caustic comments on her methods (*Photo Journal* 1864 Vol. 9 p. 87; 1865 Vol. 10 p. 117) which were perhaps not altogether unjustified. She received however praise and encouragement from G. F. Watts and other men

of the time. Her work has an interest of its own, and it is a pity that it is not more widely known. She was a woman of great power and her principles of art were far in advance of her contemporaries.

## Platinotype—W

The platinotype process was the first to give the photographer a direct control over the printing of his pictures. It was a slow and expensive process, but it was the only one that gave the photographer a direct control over the printing of his pictures. It was a slow and expensive process, but it was the only one that gave the photographer a direct control over the printing of his pictures. It was a slow and expensive process, but it was the only one that gave the photographer a direct control over the printing of his pictures.

## THE NEW PICTORIAL MOVEMENT

**Dr Emerson's Naturalistic Photography (1887)**—The expansion of a lecture by Dr. P. H. Emerson, *Naturalistic Photography*, to the Camera Club in 1886 was the beginning of the new movement. Unquestionably this book struck a powerful blow at the many conventionalities which had attached themselves to the practice of photography and had a powerful influence upon the younger pictorialists. In it he lays down that naturalism is an impersonal method of expression, a more or less correct reflection of nature wherein (1) truth of sentiment, (2) illusion of truth of appearance (so far as is possible), and (3) decoration are of first and supreme importance. He further advocated the differentiation of focus to secure separation of the planes, closer attention to the rendering of tone, greater adherence to truth through the study of nature and generally a higher and more intellectual standard.

To what extent Dr. Emerson's book contributed to the new pictorial movement that made itself evident in the late eighties is doubtful. The movement originated no doubt from the ferment in the artistic world due to the influence of the French Impressionist school which was becoming known and appreciated. The leaders of the new pictorialism were George Davison, Alexander Keighley, James Craig Annan, A. Horsley Hinton and Alfred Stieglitz, and the consensus of opinion is that the first visible sign of the break with the older Victorian tradition is to be found in Davison's picture *An old farmhouse* or as it was called later *The Onion field*. This famous picture received the Photographic Society's medal in 1890. The council of the society consisted mainly of scientists who, beyond holding the annual Exhibition, did little to encourage pictorial work and as a result the new body of pictorialists soon came into conflict with them.

There was a secession and many whose interests were purely pictorial left the parent society to band themselves together as *The Linked Ring* with definitely pictorial aims and interests, one of which was the holding of a separate exhibition to be known as *The Salon*. Although the society's neglect of pictorial interests was advanced at the time as the reason the schism originated in a quarrel in which H. P. Robinson, Davison and the assistant secretary of the Photographic Society were involved. The establishment of this energetic new organisation brought about a veritable renaissance which received a further stimulus by the revival of Pouncy's Gum Bichromate process in a workable form by Ladeveze, a Frenchman, and by Alfred Maskell and others in England. At last the pictorialists had a really controllable

our first process. Due to the influence of the French and other in France to produce a large series of work of a revolutionary kind. Two of the first pictures were the 'Horse and Rider' and 'Melton Meadows' by Alex Knight. The 'White Seal'.

**American Influence.**—By the end of the century the first signs of the new style were clearly visible but a new era began in 1905 with the formation of the British Photo-Club and the RPS. The collection of some 360 prints by members of the Royal Photographic Society. The exhibition proved a sensation and had a tremendous influence on British photography with the result that during the next few years pictorial photography retained a high standard which has never quite touched again.

The influence that was behind this wonderful American development was that of a man of genius Alfred Stieglitz who after studying photography in Berlin returned to New York about 1890 to begin his great task of building up an American School of pictorial photography upon foundations that were practically non-existent. The inspired achievements of the Americans from 1900 to 1908 are eloquent testimony to the success of his great work for which in 1914 the Royal Photographic Society awarded him its Progress Medal a unique distinction for a pictorial photographer. It is necessary to name only F Holland Day, Yarnall Abbott, Gertrude Kasebier, Eduard Steichen, Frank Eugene, Clarence White, Alvin Langdon Coburn, Mrs Annie Brigman and George H. Seeley to realise the number of photographers of real vision and genius who responded to the inspiration of Stieglitz.

Although the brilliance of the Americans overshadowed to some extent the work of the British school that too reached a high level of excellence during the same period whilst its effort has been more sustained so that in the subsequent twenty years British pictorial photography has taken more and more the leading position in the world's work rather perhaps by reason of its sanity and sober pictorial excellence than by any quality of brilliance or progressive novelty of outlook.

The development of the colour sensitive plate culminating in the Panchromatic plate in 1906 affected pictorial photography but little and even twenty years later although most photographers use negative material that is orthochromatic to some extent they are somewhat conservative in their attitude to panchromatics principally because they are apt to give harsh results unless developed with more discretion than the average photographer possesses.

The introduction of the soft gradation Panchromatic plate by the Ilford Co. in 1918 may serve to break down this prejudice and get rid of the bugbear of over-correction which in most cases would be described more correctly as over-development.

**The Oil Process.**—A new method of printing the Oil process was introduced by G. E. H. Rawlins in 1904 and worked out by himself, Demachy in Paris and C. F. Inston in Liverpool. Based upon the action of light upon chromated gelatine it consists in applying an oil pigment such as lithographic or printing ink to the damp gelatine surface by means of special brushes and so building up an image whose development can be controlled and modified according to the skill of the worker.

A very useful modification of this known as Bromoil was worked out by C. Welborne Piper in 1907. In this a Bromide print or enlargement is bleached in a special solution and can then be inked up in the manner described. The latest modification consists in transferring the inked image by means of pressure to a sheet of plain paper. This is the transfer process and bids fair to be the chief pictorial printing medium of the future for the image then consists of a permanent pigment on pure paper the whole process is under the photographer's control and as many printings can be superimposed as may be necessary to secure the desired result.

#### PROGRESS OF PICTORIAL MOVEMENT

**Great Britain.**—In 1909 internal dissensions brought about the disruption of The Linked Ring and the exhibition of that year was the last of the original Salon. A few of the members formed themselves into a Secession which held a small but notable exhibition in 1910 which, however, was not repeated, and the other supporters of the Salon came together under the lead of F. J.

Mostimer and established in 1911 the London Salon which still continues. Amid all these changes the RPS Exhibition continued its even way. For a year or two after the secession in 1892 he succeeded in holding aloof but gradually they came back and most of the prominent pictorialists exhibited at both shows so that there was little to choose between the two.

During the World War and especially towards the end pictorial photography was carried on under great difficulties and the Exhibitions fell almost to the vanishing point. Since then a gradual revival has set in but it has taken nearly ten years to return to normal. The feature of late years is the levelling up that has taken place in the world of the general body of photographers as well as the great increase in its practice. To the RPS Exhibition of 1918 460 workers sent in more than two thousand prints.

The position of British photography to-day is largely the result of the highly organized nature of its pictorial efforts. The very large number of photographic societies all over the Kingdom their grouping into Federations and unions which cater for their needs and stimulate their activities the scheme by which a large number of the societies are affiliated to the Royal Photographic Society for the same ends and lastly the RPS itself which has become not only the parent society of the British empire but to an ever increasing extent of the American and continental pictorial groups and associations as well. The numerous photographic exhibitions held in Great Britain of which the most important are the RPS Annual Exhibition the London Salon the exhibition of the Professional Photographers Association the Salon of the Scottish Federation the Northern Exhibition and the Midland Salon have done much to foster the growth and appreciation of pictorial photography and afford the British public greater facilities to see good pictorial work than can be found in any other country.

**America** has several notable Salons held annually at Pittsburgh Buffalo Los Angeles San Francisco and Seattle. The work there is inclined to be decidedly experimental and novelty is perhaps more sought after than beauty though this may be merely a stage in the development and the prelude to the evolution of a style and school such as was possessed in the great days before 1908.

**France** under the inspiration of Robert Demachy in 1900 was the leader in photographic pictorialism but since the great men of that period retired from active participation in the foreign exhibitions the French school is less known outside that country than formerly although an exhibition of work by members of the French Photographic Society at the RPS in 1926 revealed several new pictorialists of eminence.

**Germany and Austria** have during the past thirty years always held a prominent place in the pictorial movement with individual characteristics of their own. Before the World War the pictures of Duhrkoop, Perscheid, Kuhn and the large gum prints in colours by the brothers Hofmeister were notable features of the leading exhibitions. Since the World War the Germans have not participated to any great extent in foreign exhibitions, but the work of Otto Vogelsang of Pomerania, Dr. Koppitz of Vienna and Franz Drtikol of Prague has shown that there are pictorialists of the front rank.

**Other Countries.**—Italy has progressed rapidly in recent years under the inspiration of the *Gruppo Piemontese* of Turin and the work of the new school is virile whilst based on the best traditions. Spain possesses one pictorialist of eminence in J. Ortiz Echague but no national school whilst in the Scandinavian countries the pictorial work appears to be done entirely by the professional photographers of whom Aage Remfeldt of Oslo and Ferdinand Flodin and Dr. H. B. Goodwin of Stockholm are the best known. In Holland and Belgium there are several active workers and Borrenbergen and Berssenbrugge in the former and Leonard Misonne in the latter are well known at the exhibitions in this country.

#### COLLECTION OF PICTORIAL PHOTOGRAPHS

The organized collection of pictorial photographs generally seems to have presented few attractions to any public institutions or to individuals and it is a regrettable fact that no complete record exists of the achievements of the past. The importance to posterity of such a record was not realised in the early days and in

[illegible]

In 1911 the Prince of Monaco, who had, inter alia, apparently formed a collection of native objects, gave the Photogram Society of London to form the nucleus of a permanent collection. The Society appointed a committee on the Prince's suggestion at that point, but no permanent board at the appropriate time was ever formed. If the prints were ever received there is no trace of them now. I was told until after 1960 that the idea of forming a permanent collection was revived and the line taken was to acquire annually the pictures which received medals at the exhibition but in that small effort soon expired and the collection grew in disrepute and finally languished.

In 1914, however, the President, who for once was a pictorialist, organised an effort to make the collection worthy of the society. A rapid response was received, many pictures of great historical and pictorial importance were secured, gaps were filled, a curator appointed and the Society's Permanent Collection, although by no means complete, is by far the largest and most representative in the world. The addition of the Holcroft collection adds greatly to its value and importance. Collections of photography have been made by the Smithsonian Institution, Washington, U.S.A. and by the State Museum in Berlin and in recent times Mrs. Milson, a former Lady Mayoress of Sydney, N.S.W. formed a collection of pictorial photographs to become the basis for a permanent collection in Australia, but none of these can compare in size and importance with the R.P.S. collection which contains examples of the work of all the most notable photographers from D. O. Hill to the present day. The further expansion of this collection is assured by the recent gift by Mr. Stephen H. Tving of New York of a fund for the purchase annually of outstanding examples of photographic art. The administration of this fund is placed in the hands of the Pictorial Group of the R.P.S., an organization within the Society specially designed to encourage and foster pictorial interests in every possible manner.

**Photographic Press Weekly and Monthly**—This while dealing with pictorial matters has catered chiefly for the general reader and the publications dealing exclusively with pictorial interests have been comparatively few. The first of this nature in Great Britain was a series of monographs on the work of the leading pictorialists of the day each volume being devoted to the work of one man and illustrated in photogravure by four of his pictures. The whole was issued in 1890 under the title of *Sun Artists*. In 1895 the proprietors of *The Photogram* a monthly magazine issued a special volume devoted to an account of the photographic activities of the year in this and other countries with 90 illustrations of selected pictures. This has grown to be a feature of annual interest and under the editorship of F. J. Mortimer FRPS is now the principal record of the photographic pictorialism of the world. A volume of somewhat similar aim but limited to the pictorial work exhibited at the RPS has since 1906 been issued under the auspices of the Society by F. C. Tilney FRPS who supplies a critical commentary on the pictures reproduced. In addition the Society issues in the October number of its *Journal* an account of the year's work both pictorial and scientific with abundant illustrations. Of late years the *Société Française de Photographie* and the *Gruppo Piemontese* have issued sumptuously illustrated records of the Salons held by them annually which constitute valuable records of the work done in their respective countries, and now Japan is doing the same on a slightly less ambitious scale in the *Japan Photographic Annual*. The most beautiful of all these records of photography, however

The author of the article in the our volume of *Camera*  
 Magazine is the first to point out the fact that  
 the reproduction of the photograph is not a reproduction of the  
 original photograph but a reproduction of the reproduction of the  
 original photograph. The author of the article in the  
 Magazine is the first to point out the fact that the  
 reproduction of the photograph is not a reproduction of the  
 original photograph but a reproduction of the reproduction of the  
 original photograph.

[illegible]

## SUBMARINE PHOTOGRAPHY

Water is often so calm and clear that it might seem easily possible for one above its surface to photograph fishes or other objects beneath it. This may indeed sometimes be done but usually the attempt results in complete failure. The explanation is simple. At the moment of exposure the rays from the near submerged object are sharply focussed upon the plate. But at the same time more intense light from distant objects out of focus after being reflected from the water's surface reaches the plate also which when developed consequently shows nothing. To set up an opaque screen shading the water's surface above the subject overcomes the difficulty. Through the shaded area as through a window one may photograph what lies below. However the method is limited in its application. When the water exceeds 3ft in depth it is usually better to use a submerged camera.

Dr L. Boutan of Paris—pioneer in this field—between the years 1893 and 1898 attempted submarine photography at the Roscoff laboratory in Brittany with cameras of several sorts and appropriate and ingenious subsidiary apparatus. One of his cameras made of metal was directly submersible. Sea water reached its interior bathing both lens and plates. Although the result obtained was unsatisfactory because no thoroughly suitable lens was available the principle seemed good to him. Other trials in which the camera was enclosed in and protected from the water by a metal box through a glass window in which it looked out were by comparison highly successful. This sort of apparatus variously modified has been used in all later work.

Boutan's cameras were of the simple detective type. Reighard ten years after at Tortugas Fla. first used a reflecting camera protected in a water tight box weighted down with lead till the window through which the camera looked was submerged although the focussing hood remained above water and permitted him at all times to see what might be in the field. Excellent pictures were obtained within wading depth beyond which he did not go.

Williamson Brothers commercial motion photographers probably as an independent invention enclosed not only the camera but the photographer as well in a chamber suspended by a non collapsible open tube from a floating scow. Perfect pictures of the sea bottom and animals in shallow water were obtained in the clear water of the Bahamas as the scow stood still or was towed slowly along. These writers must be credited with the first attempt to secure a photographic record in colour of submarine life in its natural setting. By using selective filters they secured films which when projected upon the screen gave an idea of the variety of colour upon a tropical reef, but since the yellows registered as reds the attempt can scarcely be considered entirely successful.

Historical — E W r D i P

[illegible]

It was the first photograph of a star which was  
of Vega taken at Harvard Observatory on July 1800.  
The first photograph of a planet was taken in 1840  
and it was the first photograph of a comet which was  
collected in the year 1847. The first photograph of a  
planet was taken in America and England in 1847.  
In November 1847 a photograph of Uranus with its co-  
panion Alcor taken at Harvard was sent for exhibition at the  
Royal Astronomical Society by W. C. Bond an exposure of so  
seconds having been given to photograph the 6th magnitude star  
with the refractor of De la Rue at this time was making ex-  
periments on the acoustic power of Jupiter and Saturn compared  
with that of the moon but his photographs did not show any  
details of the planetary surface. Under his direction also and of  
his design a photophenograph was made and set up at Kew Ob-  
servatory for the Royal Society and the work of taking daily  
photographs of the sun that has since been carried on suc-  
cessfully at Greenwich and elsewhere began at Kew in March 1858.  
In an attempt to photograph Donati's comet of that year De la  
Rue was not successful though it was photographed by Usherwood  
of Walton Common in 1/2 sec with a portrait lens of short focus

Daguerreotypes of the sun taken by Foucault and Fizeau in 1845, and photographs of the solar eclipses of 1851 and 1854 were interesting as experiments but the photographs taken by De la Rue and by Secchi of the total solar eclipse in 1860 were the first of this kind of real scientific importance since they established beyond doubt that the solar protuberances were really appendages of the sun and not of the moon. Ten years later at the eclipse of Dec. 1870 excellent photographs taken by A. Brothers at Syracuse supplied evidence that the corona was also of solar origin and from that time a photographic picture of the sun's surroundings has always been an item in the programme of eclipse observation. A series from 1896 to 1922 is published in the *Phil. Trans.* vol. 226 A and as Appendix to vol. lxxv of the *Memoirs* of the Royal Astronomical Society.

In the years after 180 research and experiment in photography generally were made by many among these being the researches of Capt W de W Abney R E made specially for their application to astronomy. It was decided mainly at the instigation of De la Rue that photography should be used by the British expeditions in addition to visual observation for the Transit of Venus in 184 and a considerable sum was granted for the expense of the work which so far as the process was concerned was put in Abney's charge. He realized that the circumstances of the occasion would make a wet plate process in applicable and after experiments conducted at Chatham recommended the adoption of an albumen dry process using a highly bromized collodion and strong alkaline development.

Without attempting to give any complete account of Abney's researches mention of the titles of two papers by him—*On Dry Plate Processes for Solar Photography* and *On the Photographic Method of Mapping the Least Refrangible End of the Solar Spectrum*—will indicate their bearing on astronomy. These papers represent a remarkable achievement in that Abney succeeded in producing a special photographic emulsion sensitive to red light which he used to map the solar spectrum far into the infra red. The limit of Abney's measures at 0.867  $\mu$  apparently was not

I have been thinking of you a great deal lately, and wondering how you are getting on. I hope you are well and happy. I have been very busy lately, but I will try to write to you more often. I have been thinking of you a great deal lately, and wondering how you are getting on. I hope you are well and happy. I have been very busy lately, but I will try to write to you more often.

His plans for securing photographic instruments and cameras into general use about 1830, he fruitfully did so, and made considerable progress of photography in England. Circulars were circulated with the objects of which was specially significant seen from the Southern Hemisphere, here led to development. A photograph taken with a camera adapted for purposes of the great equatorial of the Royal Observatory of the Cape of Good Hope showed not only the comet but great number of faint stars around it and this at once gave David Gill H.M.A. from other the Cape the idea of the possibility of making star charts by photography. Effects of various kind followed. At Paris the brothers Henry of the National Observatory were engaged in the laborious task of plotting the position of stars found by eye observation to make charts of the stars near the Ecliptic but this work was abandoned and their efforts were devoted to making a telegraphic object glass suitable for photography. Amalie Common in England turned to the art and with a three foot silver on glass mirror took a photograph of the Orion Nebula on Jan 30th 1883 with an exposure of 5 min a feat that earned for him the Gold Medal of the Royal Astronomical Society in 1884 and was referred to as epoch marking by Abney when presenting the medal to another non professional astronomer for similar work eleven years later. A photograph of this object taken by Dr Henry Draper of New York on Sept 10 1880 is said to be the first of a nebula obtained but it is agreed that this was not a satisfactory representation. The later recipient of the medal above mentioned was Isaac Roberts a business man of Liverpool who in 1885 had made a 20 in silver on glass reflector of nearly a 100 in focal length for the purpose originally of making star charts by photography but altered his plans and devoted the instrument to photographing star clusters and nebulae. The excellent pictures produced at his observatory at Crowborough Sussex are in two volumes published during his lifetime supplemented by a third prepared and issued by his widow in 1928.

Common's photograph of the Orion nebula led through Holden to the acquisition by the Lick Observatory of a 3 foot reflector in 1895. Two mirrors made by Calver formerly owned by Common were presented to that institution by Mr Crossley of Halifax England and one of these rehured by Grubb forms the essential part of the instrument known by his name. In Keeler's hands it yielded a superb series of photographs of nebulae which for the first time demonstrated the great advantages of the reflecting telescope for certain classes of astronomical photography and led to the construction of the great modern reflectors.

**Charts of the Heavens.**—The advantage that photographs of clusters and nebulae have over visual observation is obvious. A glance at a photograph shows the whole of the object in all its beauty. The field of view of a telescope is small and a complete conception of the nebula has to be built up from successive elements. It has already been mentioned that Gill foresaw the possibility of recording the positions of stars from a single plate: the next step was to connect individual plates to make a complete survey of the heavens as had been and is the final aim and purpose of transit observing. The first effort in this direction was made by Gill who (1885-89) took photographs covering the sky from the South Pole to declination  $18^{\circ}$  S which, measured by

[illegible]

The graph I shall have proved then gives equally indisputable in every other field of spectroscopic observation. The measurement of the distance of a star from observations of its spectrum by a method discovered by Adams and Kohlschütter and developed by Adams at Mount Wilson essentially requires the determination of the relative intensity of certain pairs of spectral lines. Star light in general is far below the limiting intensity which would permit even the crudest visual observation of these intensities and this is often true of laboratory sources of light which must be studied as a means of interpreting the observations of celestial bodies. Even for the sun, which gives an abundance of light, measures are most advantageously made on photographs. In the infra red and ultra violet regions outside the limits of visual perception photographic methods alone are possible. The novel instrument known as the spectroheliograph conceived independently by Prof. Hale and M. Deslandres, director of the National Observatory, Paris, is an ingenious adjunct to spectral photography. On a plate moving behind a second slit at the rear of a spectroscope at the same rate as the image crosses the primary slit or by an equivalent device the sun is photographed by the light of a particular wave length and pictures result which show the calcium or the hydrogen alone in the successive envelopes of the sun and so add vastly to our knowledge of its structure. The help that photography brings to eclipse observation by making a complete record of the spectrum of the chromosphere or of the corona in the very short time available on such occasions that may be studied at leisure need not be dwelt on.

**Photographic Telescopes.**—In the ordinary telescopic objective the lenses are so shaped that the rays of the spectrum about the yellow are brought as nearly as possible to pass through the same point as focus for these are the rays to which the eye is sensitive but for photography it is the blue and violet rays that must be brought to a focus, for it is these that most affect the

[illegible][illegible]

The choice of aperture and focal ratio for a photographic telescope depends on the purpose for which the instrument is to be used and is determined by the same principles that apply in ordinary photographic practice. Increased focal length means increased scale or magnification in the photograph. For a given focal length increased aperture means greater brightness in the optical image and hence greater photographic efficiency which may be utilized either to reduce the exposure time or to photograph fainter objects than would otherwise be possible. For extended objects like planets or nebulae the brightness of the image is proportional to  $a/f^2$ . The photographic efficiency is independent of the linear dimensions and the chief advantage of a large instrument is that of magnification. At the same time the instrument must not be too small otherwise the power of resolution or minimum separation which varies inversely as the aperture will suffer. For point sources such as stars the diameter of the central diffraction disc of the image decreases as the aperture increases. This introduces an additional factor  $a^2$  whence the brightness is proportional to  $a^4/f^2$ . For a given focal ratio there is in this case an important gain in efficiency with increasing aperture although it is less than the elementary theory would indicate. Aberrations and absorption and reflection losses in the objective imperfections in the optical surfaces and tremor of the diffraction disc caused by atmospheric disturbances all operate in diminishing the theoretical gain.

The application of these principles to different classes of observational problems is well illustrated by some of the instruments of the Mount Wilson Observatory. For observations of the sun both direct and spectroscopic high magnification is desirable. Since there is an abundance of light the focal ratio need not be large, and further since a moderate aperture affords adequate resolution for photographic purposes the dimensions chosen for the larger Tower telescope are  $a=1$  foot  $f=150$  feet with a ratio of 1 to 150. For the efficient photography of very faint stars both the focal ratio and the linear dimensions should be as large as possible. Hence in the Hooker reflector we find  $a=100$  inches  $f=500$  inches with a ratio of 1 to 5. Under favourable atmospheric conditions the theoretical gain over the 60 inch reflector of the same focal ratio in photographing stars is very nearly attained. Aside from differences of scale these two instruments are of equal efficiency in photographing nebulae. For planets however the 100-in is practically the more effective. For the same magnification (enlarge

in the are to be reproduced in the photograph. This is done by the use of a camera which is placed at a distance from the object to be photographed. The camera is focused on the object and the light from the object is projected onto the photographic plate. The plate is then developed and the image is fixed. The image is then printed on a sheet of paper by the use of a printing press. The printing press is a machine which is used to print text and illustrations. It consists of a frame which holds the type and a platen which is used to press the ink from the type onto the paper. The printing press is operated by a hand crank or a foot pedal. The printing process is a mechanical one and is used to produce large quantities of printed material.

The limiting stellar magnitude attainable with a given instrument is shown by I. F. Ros. It does not increase indefinitely as the exposure time is extended. In order to have a perceptible image of a star it must be recorded. The contrast between sky illumination which is always present in some degree and sky illumination plus brightness of the central diffraction disk of the star image must not drop below a certain minimum value. The effect of sky illumination is determined by the ratio of the area of the sky illumination to the area of the star image. The brightness of the optical star image varies as the square of the increase in the linear dimensions increases the latter but not the former ratio. These ratios together with certain photometric constants determine the limiting magnitude attainable by prolonged exposure with any instrument. To photograph still fainter stars an instrument of larger aperture must be used.

The plate may be placed in the principal focus of the objective and the image enlarged afterwards if desired but the amount of the subsequent enlargement is limited by the grain of the original negative which is equally enlarged by the copying process. On the other hand a lens or combination of lenses may be interposed between the objective and the plate to give an enlarged image on the latter. In the Greenwich photoheliograph the image of the sun is enlarged on the plate in this way and the method is often used in planetary photography. For bright objects it is advantageous but for fainter ones the exposures required may be impractically long. The contrast also suffers but this may be corrected by subsequent copying on plates of strong contrast.

In the early days of astronomical photography the inferior performance of the driving clock of the equatorial was found to be a drawback but this has been remedied first by the introduction of electrical control and later by improved forms of driving mechanism of which the electro motor controlled by a pendulum designed by W. P. Gerrish of Harvard is an example. The slight residual irregularities are eliminated by the use of the twin instrument consisting of two parallel telescopes of nearly equal size in the same frame one of which is used visually by the observer to guide or otherwise by the double slide plateholder and duplicate guiding microscopes to be used on two guiding stars on opposite sides of the field to detect the small rotation which may occur during exposures. (H. P. H. F. H. S.)

**PHOTOGRAPHY, SPARK** see SPARK PHOTOGRAPHY  
**PHOTOGRAVURE (MACHINE)** Photogravure (machine printed) is a photo mechanical intaglio printing process. By this method prints are obtained from a plate or cylinder upon which the design is etched below the surface.

The subject to be reproduced is photographed and reticulated by means of a ruled screen the cavities varying in depth according to the tones of the original thus the solids are deeper and contain more ink than the middle tones while the high lights are represented by the paper. The characteristic of this class of printing is revealed by its velvety depths and satin like finish.

Machine photogravure was invented by Karl Klitsch who in conjunction with a firm of calico printers in Lancaster produced prints by this method in 1895 although previous to this an employee of the firm Samuel Fawcett had been working an intaglio photo-engraving process of his own. The latter assisted Klitsch in perfecting the process now known as Rembrandt photogravure. The method of producing prints by the Rembrandt process was kept a close secret and for many years those

engaged in reproductive processes had no authentic information as to how the printing plates were produced. In time however prints by similar processes were published but these at the time were not equal to those printed by the Rembrandt process.

The principle of producing photogravure prints by machine is similar to that of printing calico and wallpaper where engraved copper cylinders are used and printed on a rotary machine.

After the etching of the photogravure plate or cylinder has been completed the printing is of a mechanical character. The etched cylinder turns in a trough of printing ink of volatile qualities (sometimes a water ink is used) and as the cylinder rotates a fine steel knife known as the doctor scrapes the surplus ink from the surface leaving it clean. The cells or cavities however representing the tones of the design retain the ink which is transferred to a sheet of paper as it passes between the printing and impression cylinders.

**Preparing the Printing Surface**—From the photographs of the subjects to be reproduced negatives are obtained. These are carefully retouched and reversed positives are made from them and when necessary again retouched. The positives—usually called transparencies—have then to be planned or laid out & fixed by means of gummed tape upon a sheet of plate glass in the positions in which they will be printed.

A carbon print is next obtained on what is known as carbon tissue (a sheet of paper coated with a gelatine solution to which has been added a pigment—usually red—and sensitised by immersion in potassium bichromate squeezed on to a sheet of glass and dried). A piece of carbon tissue is cut slightly larger than the positives and placed along with the positives in a special pneumatic printing frame from which the air is extracted thus bringing the positive and tissue into close contact. These are exposed to light the positives are removed and another exposure is given to the tissue through a specially ruled screen. The screen breaks up the tones of the photograph and provides the reticulation which is necessary for all printing processes. The usual ruling of the screen is 150 or 175 lines to the inch. The carbon tissue is next soaked in water and placed on the copper plate or cylinder which has previously been made chemically clean and free from grease. The tissue is then squeezed in order to remove all moisture and air from between the tissue and the printing surface which is then dried.

**Developing**—The next operation is known as developing and is done by placing the cylinder or plate on which the carbon tissue has been fixed in a tank of water heated to about 104° F and kept agitated until the paper is soaked off and the soluble parts of the gelatine film washed away. The parts where the light passes right through the positive become hard and are insoluble whilst those parts where the light is retarded by the tones in their various gradations are more or less soluble.

When the development is completed the cylinder with all that is left of the gelatine film is removed from the water bath and thoroughly dried. This film acts as a resist to the mordant. All parts of the printing surface which are not required to be etched are protected by an acid resisting preparation. This is painted on by hand or as it is termed laked out.

**Etching**—The printing surface has then to be etched which is done by placing the cylinder in baths of varying concentrations of ferric chloride ranging from 45 to 37 Beaume. The thinner parts of the hardened gelatine acid resist are attacked first by the mordant the thicker parts requiring further etching by the weaker solutions.

It is possible to use the copper cylinders over and over again the old work being removed by grinding and polishing. In this way cylinders are prepared to receive the new work. In time however the grinding wears the cylinder but this may be brought back to its original circumference by electrolytic deposition.

**Machines**—Sometimes flat plates are used. In this instance the machine is of an ordinary flat bed type upon which a plate is mounted on a bed and covered over with ink the "doctor" scraping the surplus ink from the face of the plate back into the trough the general method however is to employ cylinders.

Recently a method has been invented whereby a thin sheet

photometric unit is that of luminous intensity. This unit is the *international candle* the magnitude of which was originally defined as the luminous intensity in the horizontal direction of a candle of specified dimensions burning at a specified rate. Many years ago this form of standard was found to be unsatisfactory and it was replaced by flame lamps of various kinds viz the Hefner in Germany the pentane in this country and in America and the Carcel lamp in France. These standards have been generally abandoned however and the magnitude of the unit is preserved by means of specially constructed electric lamps deposited

at the various international laboratories have been the world viz the  
Laboratoire Central d'Etudes et de Recherches Physico-Chimiques  
Laboratoire d'Etudes et de Recherches Physico-Chimiques  
Walton and The British Association of the candle power follows

The unit of luminous intensity is the *candle* which is defined as the luminous intensity of a source which emits equally in all directions a uniform luminous intensity of one candle in all directions. The lumen is the amount of flux emitted by such a source within a cone of unit solid angle.

The relationship is shown pictorially in fig 3 where the ideal point source is imagined at the centre of a sphere of unit radius. Since the solid angle of any cone with its apex at the centre of such a sphere is numerically equal to the area of the spherical surface cut off by the edge of the cone it follows that the cone shown shaded in the diagram embraces unit solid angle so that the flux emitted by the source within this cone is 1 lumen. Since the area of the whole sphere is  $4\pi$  times the square on the radius it follows that a uniform point source of 1 candle emits altogether  $4\pi$  lumens. Since the total flux emitted by a source is independent of the way in which that flux is distributed the total number of lumens given by a source is equal to the *average* value of its luminous intensity measured in all directions in space multiplied by the factor  $4\pi$ . The luminous intensity of a source when expressed in international candles is termed the *candle power* of the source. The average value of the candle power measured in all directions perpendicular to the geometrical axis of the source is termed the *mean horizontal candle power* (MHCP) while the average candle power measured in all directions in space is termed the *mean spherical candle power* (MSCP). It will be seen that for any source  $MSCP \times 4\pi = (\text{flux output in lumens})$ .

FIG 3—RELATION BETWEEN THE PHOTOMETRIC UNITS

**Illumination The Inverse Square and Cosine Laws**—Illumination is measured by the amount of luminous flux which reaches unit area of an illuminated surface. From this definition and the fact of the rectilinear propagation of light there follow at once the two basic laws of photometry viz the inverse square and the cosine laws. They will be most clearly understood by reference to fig 2. If BLC be an elementary cone of light emitted from a source L the area intercepted by this cone on any plane such as XY varies (1) as the square of the distance ( $d$ ) of L from the plane and (ii) as the secant of the angle ( $\theta$ ) which the normal to XY makes with the axis LA of the cone. Since the illumination produced by a given amount of flux varies inversely as the area over which that flux is distributed it will be seen at once that the illumination of a surface varies (1) inversely as the square of its distance from the source illuminating it (this is the inverse square law) and (ii) directly as the cosine of the angle between the normal to the surface and the light rays (this is the cosine law).

Now let the average luminous intensity of the source L in all directions lying within the cone BLC be  $I$  candles and let the area intercepted by this cone on the plane XY be  $s$ . Then the solid angle of the cone is equal to  $(s \cos \theta)/d^2$  and the flux  $F$  emitted within the cone is  $I(s \cos \theta)/d^2$  lumens. Since by the definition the illumination  $E$  of the surface is equal to  $F/S$  it follows that

$$E = (I \cos \theta)/d^2$$

It will be seen that the magnitude of the unit in which  $E$  is measured must depend on the unit used for  $d$ , i.e. on the unit of length. If  $d$  be expressed in feet, the unit in which  $E$  is measured is termed the *foot candle* and clearly one foot candle is the illumination produced when an area of one square foot receives one lumen of flux. Similarly if  $d$  be expressed in metres, the unit of  $E$

is the *candle* or the *lux* and one lux is equivalent to an illumination of one lumen per square metre. It will be seen that 1 foot candle = 10.76 lux.

**Brightness**—The 1 of the four fundamental photometric quantities brightness which is thus defined. The brightness in a given direction of a surface emitting light is the quotient of the luminous intensity measured in that direction by the area of this surface projected on a plane perpendicular to the direction considered. The unit of brightness is the candle per unit area of surface. Thus if a plane of uniform brightness has an apparent area of one square inch when viewed in a given direction and if the luminous intensity in that direction be 10 candles the brightness is 10 candles per square inch. Similarly if a surface has an area of two square metres and if its brightness when viewed normally is one candle per square metre it has a luminous intensity of two candles in the direction of the normal.

The surfaces of bodies may be divided broadly into two classes polished and diffusing according as they reflect specularly the light they receive after the manner of a mirror or scatter it in all directions. A surface which scatters the light which it reflects or emits in such a way that it appears equally bright in all directions is called a *perfect diffuser*. No such surface exists in perfection but good white blotting paper or ground opal glass provide a fair approximation. It is sometimes convenient to use as a unit the brightness of an ideal perfect diffuser emitting or reflecting one lumen per unit area. It can readily be shown that such a surface has a brightness of  $1/\pi$  candles per unit area. Thus the following relationships are derived

$$\begin{aligned} 1 \text{ lambert} &= 1/\pi \text{ candle per sq cm} \\ 1 \text{ millilambert} &= (0.001)/\pi \text{ candle per sq cm} \\ &= 10/\pi \text{ candles per sq metre} \\ 1 \text{ foot lambert} &= 1/\pi \text{ candle per sq ft} \\ &= 1.076 \text{ millilamberts} \end{aligned}$$

**Absorption Reflection and Transmission**—It has been said already that bodies which are not self luminous are visible by reason of the light which their surfaces reflect to the eye. It will be clear that since a surface which has an illumination of one foot candle receives one lumen per square foot its brightness would be one foot lambert if it were a perfect diffuser and if it reflected all the light it received. Actually all surfaces absorb some fraction ( $\alpha$ ) of the light which reaches them and reflect or transmit the remainder.  $\alpha$  is termed the *absorption factor* while the fractions reflected and transmitted are termed respectively the *reflection factor* ( $\rho$ ) and the *transmission factor* ( $\tau$ ). For opaque bodies it is clear that  $\alpha + \rho = 1$  while for all surfaces  $\alpha + \rho + \tau = 1$ . In general the values of these three quantities depend on (a) the direction of incidence of the light on the surface and (b) its colour. Only in the case of white or grey surfaces is the colour of the light immaterial. The brightness of a surface due to reflected light is clearly equal to  $E\rho/\pi$  candles per square foot or  $E\rho$  foot lamberts  $E$  being the illumination in foot candles and  $\rho$  the reflection factor for the particular conditions of illumination and the direction of view considered.

Every photometric measurement depends ultimately upon a measurement of the illumination produced at a surface. In the case of candle power determination the source to be measured and a standard of known candle power respectively illuminate two white diffusing surfaces in a photometer head which is in essence a device for enabling the eye to compare the brightness of these surfaces as accurately as possible. The chief conditions for accuracy are (a) that the surfaces shall be presented to the eye side by side with the finest possible dividing line and (b) that the illumination of one or other of the surfaces may be varied according to a known law so that the two may be adjusted to equal brightness. This is necessary because the eye cannot measure accurately but can only judge of a condition of equality.

**The Lummer Brodhun Photometer Head**—The form of photometer head generally used to day for accurate work is the Lummer Brodhun contrast head the construction of which is shown in fig 4(A). S is a matt white screen, the two sides of which are respectively illuminated by the two sources to be compared. Light from each side of S is reflected by the mirrors (B) total

FIG 4 - THE LUMMER BRODHUN HEAD

light from M there is no transmission through these portions just as if there were no discontinuity. The light from M is also transmitted through the e portion of the face of  $P_1$  but over the remainder the portion shown shaded in fig 4(C) it is totally reflected and emerges side by side with the light transmitted from  $M_1$ . It will now be seen that if the eyepiece E is focussed on the interface at I the appearance of the field is that illustrated in fig 4(C) the portion shown shaded being occupied by an out of focus image of the right hand side of S while the portion shown clear is filled by the left hand side of S. 4 *summary, complete symmetry of the instrument* it follows that when both sides of S are equally illuminated the field of view will appear uniformly bright and the lines of demarcation of the various parts will almost vanish if P has been skilfully constructed.

It has been found however that this is not the criterion of equality which the eye can appreciate with a maximum of precision and the accuracy of its judgment can be materially improved if the criterion is changed from equality of brightness to equality of contrast. This is easily arranged by placing two thin glass plates  $G_1$  and  $G_2$  (see fig 4[B]) so that they are respectively in the paths of the light beams occupying the patches  $R_1$  and  $R_2$  of the field of view (fig 4[B]). Owing to reflection losses at the surfaces of these plates their interposition causes the brightness of  $R_1$  to be about 9% less than that of the background to  $R_1$  while  $R_2$  is the same amount darker than the background to  $R_2$ . It will be seen at once that with this arrangement if the two sides of  $S$  differ in brightness by 1% the contrast between patch and background instead of being 9% in both halves of the field is 8% in one half and 10% in the other a difference which is much easier to detect than a simple 1% difference of brightness.

**The Photometer Bench.**—The simplest method of varying the illumination of one of the comparison surfaces in a photometer head is to move one of the sources towards or away from the head. The law of variation of illumination is then the law of the inverse square. The operation may be carried out most conveniently on some type of photometer bench. This may consist of two parallel steel bars supported at a suitable distance apart by a rigid iron framework. Upon the bars run three carriages which respectively bear the light sources and the photometer head. These carriages run on spool shaped wheels so that they move easily on the bars. They are provided with means for raising or lowering the sources and for enabling them to be turned about a vertical axis. Each carriage also bears a framework on which is engraved a line situated in the vertical plane which is at right angles to the axis of the carriage pillar. This framework moves over a graduated

[illegible]

**The Substitution Method**—A comparison lamp of known candle power is placed in the centre of the end of the bench and this candle power is read on the scale of the rod to be calibrated holding the photometer head on the two carriage rods on the bench as one unit. Thus one side of the photometer field has a constant brightness. The comparison lamp is now placed in turn at the other end of the bench and the distances can be found at which the illuminations by the two candles will give a balance with this constant brightness. The illuminations must then be equal to each other so that if the candle powers of the lamps be  $I_1$ ,  $I_2$  etc. and their respective distances from the photometer head at the position of balance  $d_1$ ,  $d_2$  etc. it follows that  $I_1 d_1^2 = I_2 d_2^2$ . Thus if one of the lamps be a standard

$I_1 d_1^2 = I_2 d_2^2$  — Thus if one of the lamps be a well standard of known candle power the candle powers of the other lamps are found at once. In all photometry it is most important that only the light directly emitted by the sources to be compared shall reach the photometer head and stray light from external sources, or that reflected from objects in the room, must be shut off by means of suitably placed black screens.

Although owing to its convenience the inverse square law is that most commonly used as the law governing the illumination of one of the comparison surface of a photometer head there are other laws which are adopted for special reasons in certain type of instruments. The cosine law is seldom employed but the proportionality between luminous intensity and area in the case of

FIG 5—PRINCIPLE OF THE SUBSTITUTION METHOD ON THE PHOTOMETER BENCH

FIG 5—PRINCIPLE OF THE SUBSTITUTION METHOD ON THE PHOTOMETER BENCH

**The Sector Disc**—A very accurate method of controlling the illumination of a surface is to interrupt the light reaching it at regular and frequent intervals. It has been found that the apparent brightness of a surface intermittently illuminated bears to the actual brightness when steadily illuminated the ratio of the time of exposure to the total time provided the intermittency is sufficiently rapid to avoid any appearance of flicker. This law is known as Talbot's law and though it has no theoretical foundation it has been proved experimentally that it holds with great accuracy for all ratios down to 3% or less. The law may be applied by placing in the path of the light to be reduced an opaque disc having a radial slot cut in it so that the light only reaches the photometer as the slot passes between it and the lamp. If for instance there are three slots in the disc each  $6^\circ$  in breadth the ratio of reduction is  $1/20$ . Such discs are exceedingly valuable as auxiliaries to other photometric apparatus but it will be clear that as their reduction ratio is fixed they cannot themselves be used to produce the variation of illumination needed in a photometer. For this purpose some form of disc with variable sectors is needed and many attempts have been made to produce satisfactory apparatus of this kind.

The mechanical construction is however very elegant and probably the most satisfactory one for the correction that in which the observer must correct his estimate of light intensity. Fig. 6 shows the position of the apparatus. The light from the lamp is reflected vertically downwards by the mirror and is received in the circular disc which is reflected so that it remains stationary. The elliptical surfaces may be mirrors or prisms, the 45° angle of rhomboid prism is illustrated. In this case the four surfaces are rigidly fixed to one another in the relative positions shown and the combination is rotated about its horizontal axis. It will be seen that the effect at the photometer surface *P* is precisely equivalent to that which would be produced by lowering the disc and spinning it in the usual way. As however the disc remains stationary there is no difficulty whatever in making it easily adjustable by the observer while a setting can be at once read off by having a scale on one disc and an index line on the other.

FIG. 6—BRODHUN SECTOR DISC

**Sub standard Lamps.**—The sub standards used for candle power measurement are usually tungsten filament lamps of special construction such as that shown in fig. 7. Great care has to be taken in the manufacture of these lamps so as to avoid fluctuations of candle power due to loose contacts between the filament and its supporting hooks, the bulb too has to be specially selected so that there are no striations in the glass to cause slight alterations of candle power as the lamp is rotated through a very small angle on either side of the position adopted for the standardization measurement. The candle power of such a lamp is determined at a standardizing laboratory by comparison with the fundamental standards. The value of candle power measured is that in the direction normal to the plane of the filament when a given voltage is applied to the lamp contacts or when a given current is passing through the filament. These quantities have to be very accurately controlled since in the case of a tungsten filament a 1% change of voltage or a 0.5% change of current produces a change of about 5% in candle power.

**Flux Measurement.**—Owing to the fact that most light sources are now rated in lumens instead of in candles (see the *British Standard Specification for Electric Lamps* issued by the Brit. Engineering Stds. Assn.) the measurement of luminous flux has now become an even more important operation in every day photometry than the measurement of luminous intensity. The fundamental method of finding the flux output of a source is to measure its candle power in a very large number of directions uniformly distributed in space and thus to obtain the mean spherical candle power which when multiplied by  $4\pi$  gives the flux in lumens (see p. 840). This long and tedious process may be avoided in the case of certain sources such as a tungsten filament vacuum lamp of ordinary filament form when the light is distributed fairly symmetrically about the axis. Such a lamp can be spun while the photometric measurements are being made so that the figure of candle power obtained at any given angle with the axis is in reality the mean value in all directions making this angle with the axis. It is therefore only necessary to make measurements in a limited number of directions say 20 which lie in a single plane passing through the axis of the lamp.

FIG. 7—TUNGSTEN FILAMENT STANDARD OR SUB STANDARD LAMP

Apparatus suitable for this purpose is shown in fig. 8 which is almost self explanatory. The lamp is mounted in a holder which can be rotated mechanically at a speed of say 150 revolutions per minute. The mirror system can be turned by hand about the horizontal line passing through the centre of the lamp, the photometer head and the comparison lamp. It can be shown that if the directions in which the measurements are made be suitably chosen the arithmetic mean of the individual candle powers gives the

mean spherical candle power with satisfactory accuracy. Such a lamp may be used as a sub standard of luminous flux and all that is now required is a method for measuring the flux output from more irregular sources by comparison with this sub standard.

**The Sphere.**—The method which is almost universally adopted to day is based on the demonstrable fact that if a source of light be placed inside a hollow sphere covered internally with some perfectly diffusing coating the same amount of light is received at all parts of the sphere surface by reflection from all the other parts. The light received directly from the source naturally differs according to the candle power distribution of the source but the light which has been reflected once or more often from the walls of the sphere is distributed perfectly uniformly no matter how unsymmetrical the original distribution from the source itself may be.

It will now be clear that in order to compare the total flux from two sources of light it is only necessary to place them in turn within a sphere of the kind described to screen a small portion of the sphere surface from direct light and to measure the illumination of this screened area in the two cases. The ratio of the illuminations will then be strictly equal to the ratio of the flux outputs of the sources. There are of course certain precautions which must be observed in the practical application of the method owing to the unavoidable departures from the ideal conditions assumed in the theory. The chief of these departures are (1) lack of perfect diffusion by the internal coating of the sphere and (2) the interference with the reflected flux brought about by the presence not only of the lamp and its accessories but also of the screen necessary to shield the measured part of the sphere surface from the direct light of the lamp.

The illumination of the screened area of the sphere surface may be measured by any convenient method. It is clearly unnecessary that this measurement should be absolute since only a ratio is involved. One method is to have a small opening in the sphere and to cover this with a window of opal glass or some other translucent material. The luminous intensity of the outer surface of this window in the normal direction is then measured by means of a photometer head and comparison lamp moving on a bench attached to the sphere. Alternatively the sphere opening is left uncovered and the luminous intensity of that portion of the sphere opposite the opening is measured.

The difficulty of constructing a sphere has led to the frequent adoption of a cube as a sufficiently near approximation for work of moderate accuracy. When a cube is used the light source should be placed in the centre with its axis of symmetry perpendicular to the line joining it to the window, the latter being in the centre of one face of the cube. It is clear *a priori* that if the light distributions from the sources to be compared are exactly the same the form of the enclosure employed is immaterial. So long therefore as the distributions do not differ too much a cube gives quite satisfactory results.

**Illumination Photometers.**—The third photometric measurement of importance is that of illumination. This is now so universal in illuminating engineering that many different types of portable photometer have been designed as illuminometers. Although these differ in design each consists of three essential parts viz (1) a test plate or standard surface placed at the spot at which the illumination is to be measured and generally but not always detached from the remainder of the instrument (2) a surface inside the instrument which is illuminated by a small battery lamp in such a way that its brightness can be varied at will by the observer and (3) some form of comparison device for

FIG. 8—MEASUREMENT OF MEAN SPHERICAL CANDLE POWER (POINT TO POINT METHOD)

FIG 9 — HOLOPHANE LUMET R

A piece of opal is placed near the end of the tube. The brightness of the opal is compared with that of a standard tube by means of a small Lummer Froehner cube viewed through a piece attached to the side of the tube. An inverse square scale is attached to the rod and the constant of the scale is adjusted to unity by previous calibration.

An instrument in which the inverse square law is not employed is the *Holophane luminometer* shown in the figure. The lamp L is enclosed in a white end box of hollow cylindrical form. This box is provided with a window of diffusing glass W the light from which illuminates the opaque outer parts of the comparison screen S. The eye views the test surface T through the central transparent part of S and the two parts of the field are adjusted to equality by altering the exposed area of W. This is achieved by means of a cylindrical shutter which can be rotated about the lamp enclosure by means of the handle H. The shutter is provided with an opening of the form shown in the figure. It will be clear that if W is uniformly bright the scale of the instrument will consist of two parts, one corresponding to each of the breadths of opening the scale being even within each part.

In most illumination photometers the scale of the instrument may be extended by the provision of neutral glass screens with transmission factors of one tenth. If these are inserted between the test surface and the eye the scale is extended upwards the instrument reading having to be multiplied by 10 or 100 according as one or both of these screens is inserted. If the screens are inserted between the internal lamp and the comparison surface the instrument reading must be divided by the appropriate factor. The lamp is supplied from some form of portable battery preferably an accumulator. A rheostat and a voltmeter or ammeter are provided for adjusting the current through the lamp to the value at which the instrument was calibrated. This adjustment has to be made with the greatest possible care since owing to the characteristics of the small battery lamps which have to be used an error of 1% in the current setting may result in an error of as much as 10% in the readings.

The calibration of every portable photometer should be checked at frequent intervals. This may be done by setting up the test surface at the zero point of a photometer bench and placing a sub standard of known candle power at convenient distances from it so as to give even values of illumination at the surface. The test surface should approximate as closely as possible to a perfect diffuser. Ground opal glass or sandblasted opaque white celluloid are frequently used.

**Measurement of Brightness and Reflection Factor**—Any illumination photometer which employs a detached test surface may be used for measuring the brightness of a surface or its reflection factor if it is not self luminous. This will be made clear by means of an example. When the instrument is set to a reading of say  $E$  foot candles a balance is obtained when the illumination of the test surface has this value. If now the reflection factor of this surface be  $\rho$  its brightness under these conditions as  $E\rho/\pi$  candles per square foot or  $E\rho$  foot lamberts. Hence if, when the photometer is sighted on any other surface a balance is

[illegible]

**Heterochromatic Photometry**—No distinction can be made of wavelength here at all due to its being photometric rather than visual. A difference occurs between the lights to be compared. The monochromatic lamp gives light which is much bluer than our air lamp proportionately blue to that given by the carbon arc lamp.

Since the primary photometric standard is a carbon filament electric lamp operating at an efficiency of about 45 watts per candle it is clear that at one time or another in the measurement of modern light source large colour differences have to be bridged with as little loss of accuracy as possible. There are three generally recognised methods of doing this, viz. (i) the candle method, (ii) the flicker method and (iii) the colour filter method based on spectrophotometry. Each of these methods will be described briefly in turn but mention must first be made of a peculiarity of the eye which complicates the problem. The curve shown in fig. 1 gives the relative response of the eye to equal amounts of energy at different parts of the spectrum. This curve however only applies when the brightness of the field of view is 0.15 candle per square foot or over. Below this limit the curve shifts gradually to the left so that at low brightnesses the maximum is at a wave length of about  $505 \mu\mu$ . It follows that if two fields are illuminated one by red and one by green light it may quite well happen that when the brightness or both fields is high the red may appear the brighter of the two while if both be reduced in brightness in the same ratio the balance may appear to shift over so that the green may appear brighter than the red. This effect is known as the Purkinje effect and it has to be guarded against by ensuring that the brightness of the field of view is well in excess of the limiting value mentioned above.

In the cascade method of heterochromatic photometry the colour difference between the two lights to be compared is divided into a number of small steps by the interposition of other sources giving lights of intermediate colour. The method however is not entirely satisfactory since clearly an observer who weights the whiter light will do so throughout the series of comparisons and so his errors at each step will add up in the final result.

**The Flicker Photometer.**—The flicker method depends on the fact that when the field of view is illuminated alternately by lights which differ in colour and in intensity flicker due to colour difference vanishes at a lower speed than flicker due to brightness difference. A photometer head constructed on the flicker principle is designed so that the two surfaces which make up the comparison field are presented to the eye not side by side but one after the other in rapid alternation. At low speeds the field is observed to flicker whatever the position of the photometer head but as the speed is raised the flicker gradually decreases until finally it can be made to disappear at one position of the head only. If the speed be maintained at this critical value a slight movement of the head from the position of balance causes a flicker to appear. The critical speed depends on the colour difference between the lights being naturally higher the larger the difference. Any increase in speed beyond that just necessary to

remove flicker the position of balance results in a decrease of sensitivity. It is therefore a disadvantage of a flicker photometer that it has to be used with accuracy and rapid period adjustment.

It is by no means self-evident that the results obtained by this method will agree with those obtained either by the cascade method or by the comparison method involving the whole colour

FIG. 10—FLICKER PHOTOMETER

difference and carried out by a large number of observers using say the Lummer Brodhun photometer. Much experimental work has been done on this subject and it has been found that the two methods are in agreement when the following conditions are complied with in the flicker measurement: (a) a flicker field of about 2° diameter and (b) a field brightness of about 8 candles per sq metre. Since a flicker field is very small and is most tiring for continuous work, the flicker field should be surrounded with a steady extended field of the same or slightly lower brightness.

Many different types of flicker photometer have been developed. Of the more accurate the one shown in fig. 10 is perhaps the simplest in principle, and will serve to illustrate the method. S is a white surface illuminated by way of the total reflection prism P by the light from one of the sources to be compared. W is a sector disc which can be rotated at any desired speed about a horizontal axis. Its surface is white and is illuminated by the other source of light so that when viewed by the eye at E the field of view seen through the small aperture A is alternately occupied by W and by S. A is of such a size as to subtend an angle of 2° at E. It is cut with a sharp (back bevelled) edge in a concave surface F which is evenly illuminated by the small lamp L. L is adjusted to give F a brightness of about 8 candles per square metre and the distances of the sources to be compared are then arranged so that the brightness of the field at A has approximately the same value. The test lamp and photometer are then fixed and measurements are made by moving the comparison lamp the speed of rotation of W being reduced until flicker can be made almost to disappear. Settings of the comparison lamp are then made to the point of minimum flicker. It will be noticed that the criterion of equality used in this instrument is not disappearance of flicker but minimum flicker as it has been found that in practice this gives a rather more sensitive test of the balance point.

**The Spectrophotometer**—The third method for overcoming a colour difference in photometry is to place between the photometer head and one of the sources of light a sheet of some transparent medium of such a colour that it produces a colour match with the light from the other source. If then, the transmission

factor of this medium be known for the light given by the source with which it is used the problem is solved. The only method of obtaining this information is to determine (a) the spectral energy distribution of the source and (b) the transmission factor of the medium at each wave length. The overall transmission factor  $\tau$  is then given by  $\int \tau_{\lambda} E_{\lambda} d\lambda / \int E_{\lambda} d\lambda$  where  $E_{\lambda}$  is the energy emitted by the source in a given wave length interval at wave length  $\lambda$  and  $K_{\lambda}$  is the corresponding luminosity factor.

The instrument used for determining both the above sets of data is called a *spectrophotometer* since it is essentially a device for enabling the intensities of two lights to be compared at any given part of the spectrum instead of as a whole. Every spectrophotometer therefore consists of two parts: (1) a spectrometer (see SPECTROSCOPY) for enabling any given wave length interval of the lights to be isolated and (2) some device for causing the portions of the lights so selected to illuminate the two parts of a comparison field and a means for altering the brightness of one part of this field.

The principle will be made clearer by means of an example. Fig. 11 shows diagrammatically the Lummer Brodhun instrument which consists of an ordinary spectrometer with the addition of a second collimator C and a Lummer Brodhun cube. The latter is constructed similarly to the cube used in the ordinary photometer head (see p. 841) but the form of the field is that shown in fig. 11. The two sources to be compared respectively illuminate the slits of C<sub>1</sub> and C<sub>2</sub> which may be covered with diffusing glass. For the adjustment to a photometric balance various devices may be used e.g. a variable slit in one collimator, alteration of the distance of one source from its slit, a sector disc or neutral wedge in one beam or a pair of Nicol prisms (one capable of rotation through a measurable angle) mounted in one of the collimators. The last mentioned device is used in the Brace Lemon instrument which is a modification of the Lummer Brodhun spectrophotometer, the dispersing prism being used also to form the comparison field. This prism is shown in fig. 11. As in ordinary photometry the substitution method is generally employed. The source used as a standard of spectral distribution is frequently a tungsten filament vacuum lamp since the spectral distribution of this type of lamp is very closely determined by its efficiency. Alternatively any suitable lamp may be used the spectral distribution of which has been determined at a standardizing laboratory.

11B—BRACE LEMON PRISM

at various times to develop some physical instrument which can be used instead of the eye for making photometric measurements. The instruments proposed may be divided roughly into three classes. The first of these includes the vast number of chemical photometers in which the illumination is measured by the rate of change it produces in the constitution of some chemical mixture. This form of photometer survives in the photographic

#### Physical Photometers—

Many attempts have been made

The first part of the paper is devoted to a review of the literature on the subject of the effect of the rate of interest on the rate of investment. It is found that the effect is ambiguous, and that the results depend on the assumptions made regarding the relationship between the rate of interest and the rate of investment.

The second class of physical photoelectric cells depends on the high conductivity of the electric conductors of the elements when illuminated. A sensitive selenium bridge (fraction of milliohm cell) may be made by winding four strands of iron, nickel or platinum wire round a net or some good material on which has been covered on one side with a thin layer of purified amorphous selenium. If two alternate strands of wire are then removed the remaining strands are separated by a large strip of selenium of the same breadth as the diameter of the wire. By heating the bridge to a temperature of about 120°C for five minutes or longer the selenium is changed to the metallic form and the conductivity of the path between the wire then varies with the illumination of the bridge. Many other forms of cell have been developed for various purposes. This type of physical photoelectric cell is not only subject to the disadvantage that its luminosity curve is different from that of the eye and is moreover not the same at all intensities of illumination but it has the additional defect of a lag both in response to stimulation and in recovery after the illumination has been cut off.

**Photoelectric Photometry**—The most promising form of physical photometer is the photoelectric cell described elsewhere (3 PHOTOELECTRICITY). Although the luminosity curve of any such cell is very markedly different from that of the eye and is moreover slightly different even for two cells made similarly with the same photoelectric metal it has been found that a combination of a potassium cell with a suitable yellow filter (Wratten K3) gives a curve which approximates to that of fig. 1 sufficiently closely for a device of this nature to be used as a physical photometer.

Various methods may be employed for carrying out a measurement with such a cell filter combination. The simplest is to have the combination illuminated in succession by the sub standard and the lamps to be measured and to balance the photoelectric current in each case by that from a simple photoelectric cell illuminated by a comparison lamp mounted on a bench (see fig 12). The two cells with their batteries are connected in a Wheatstone bridge arrangement with a sensitive electrometer and the distance of the comparison lamp from the cell it illuminates can be altered until the electrometer ceases to show a deflection. The illumination of the cell filter combination is

FIG 12 — PHOTO ELECTRIC PHOTO  
METER

same law connecting photoelectric current and illumination. It is unsafe to assume that this is the case over a very extended range of illumination so that the sub standard and the test lamps must be arranged to give illuminations of the same order at the cell filter combination. In the case of a measurement of luminous intensity this can be done quite easily but when the cell is being used in combination with a sphere or cube for the measurement of luminous flux some auxiliary means must be adopted for adjusting the value of the illumination. A sector disc may be used since Talbot's law is rigorously obeyed by a photoelectric cell, its response to light being practically instantaneous. For increasing the sensitivity of a photoelectric cell, a three-electrode valve is often

CELESTIAI

The first step in the preparation of the star catalogue was the determination of their relative positions by means of the method of triangulation. The first catalogue of stars published by Hipparchus in 130 B.C. which has probably been forgotten for you is the first catalogue of stars to the unaided eye. It is divided into six classes or magnitudes. The first being designated first magnitude and those just visible to the naked eye to the sixth magnitude. Each class was further divided into three subclasses. This process of arranging the stars by even images (with the unaided eye at first) and subsequently with the aid of telescopes was further developed by Flamsteed and de la Hire and culminated in the work of Argelander, Schenkel and Kruger who published three catalogues (1896) of celestial coordinates and magnitudes known as the *Bonn Durchmusterung*. This catalogue included the enormous number of 341,334 stars. An additional volume containing (1901) stars south of the equator was published in 1896 and the work was further extended in the southern hemisphere by B. A. Gould, J. M. Thorne and others. In the *Bonn Durchmusterung* or B.D. each magnitude is subdivided into ten divisions a decimal notation being used.

So far no attempt was made to define the quantitative relationship between different magnitudes. In modern times a definition due to Pogson has arisen and we define a difference of one magnitude between two stars as meaning that the light that reaches us from the first star is  $k$  times the light which reaches us from the second. The constant  $k$  is chosen so as to make a difference of five magnitudes correspond to a light ratio of 100 and this means that we must have  $\log_{10} k = 0.4$ . We cannot observe all the radiation emitted by a star. If the instrument used for registering the light be the human eye it will not respond to radiation either in the extreme ultra violet end of the spectrum or in the extreme infra red. Now if two stars are of different colours the proportion of the whole radiation represented by the light which affects the eye will be different for the two stars and the adoption of the above definition as it stands would lead to difficulties. We can retain it however for stars of the same colour and then as far as visual magnitudes are concerned we define two stars of different colour as being of the same visual magnitude when they appear equally bright to the eye. With the introduction of photographic methods a photographic scale has arisen defined in the same way two stars being of equal photographic magnitude when they produce equal photographic effects. Reference will be made below to certain difficulties arising out of these definitions. With regard to the zeros or starting points of these visual and photographic scales the zero of the measured scale of visual magnitudes has been fixed so that the magnitudes agree approximately with those in the B.D. for the mean of stars down to the sixth magnitude whilst the zero of the photographic scale is defined so that for the white stars (of spectral type A<sub>0</sub>) of the sixth magnitude (between visual magnitudes 5.5 and 6.5) the visual and photographic magnitudes are equal.

The actual methods of procedure both visual and photographic will be given in outline later in this article. In recent years an enormous stimulus has been given to stellar photometry by the realization that it can lead us to good estimates of the distances of remote objects. It was pointed out by Hertzsprung (*see* STAR), that the period of certain variable stars was related to their absolute magnitude, *i.e.*, to the magnitude that they would appear to have when viewed by an observer at a certain standard distance. By observing the period the absolute magnitude can be deduced, and then provided the apparent magnitude has been measured the distance of the star can be inferred. The discovery and elabo-

ration of the method which has been followed in the photometric observations. The magnitude of the stars is determined by comparison with the magnitude of the pole star in the case of the brighter stars and with the magnitude of the star  $\alpha$  in the case of the fainter stars.

#### MODERN WORK ON VISUAL MAGNITUDES

The observations made on visual magnitudes have been carried out in a systematic manner in the southern hemisphere (but a considerable amount has been accomplished at Potsdam) since the publication of the Harvard Photometry (Harvard Annals vol. 61). This catalogue contains the computed magnitudes of 910 stars in the field of view of the Harvard Photometer. A further catalogue (Harvard Annals vol. 54) gives the magnitudes of 366 stars fainter than 6.5. The instrument used at Harvard was the meridian photometer designed by the late Prof. Pickering. The principle underlying the instrument is the presentation of two stars in the field of view the light from one being varied by a Nicol prism until the two stars appear of equal brightness. The ratio in which the incident light has been varied is read off from the scale through which the Nicol has been rotated and the difference of magnitudes of the two stars thus obtained. The stars were all compared with a standard star which was the Pole star in the case of the brighter stars and  $\alpha$  Ursae Minoris for the fainter one.

The photometer (Harvard Annals vols. 14 and 23) consists of two telescopes placed side by side pointing due east the light from the stars on the meridian being reflected into them by two mirrors inclined at an angle of  $45^\circ$  to this direction. If there were a star exactly at the Pole one of these mirrors would be absolutely fixed and would constantly reflect the light of this star down the axis of its telescope in practice a slight motion can be given to the mirror so as to keep in view the polar star selected as the standard of comparison. The second mirror (which projects a little beyond the first so as to obtain an unobstructed view of the meridian) can be rotated round the axis of the telescope by means of a toothed wheel gearing and can thus be made to reflect any star on the meridian down the second telescope. It is also provided with a small motion in the perpendicular direction so as to command a degree or two on each side of the meridian. Near the common eyepiece of the telescopes there is a double image prism which separates the light received from each into two pencils the pencil of ordinary rays from one object glass is made to coincide with that of extraordinary rays from the other and the two remaining pencils are excluded by a stop. The two coincident pencils then pass through a Nicol prism to the eye of the observer who by rotating the prism round its axis can equalize them at a definite reading depending on their relative intensities. This reading gives in fact the difference of magnitude between the two stars selected for comparison. It may be remarked that the position of the double image prism is important. It should be just *within* not *at* the common focus this position prevents any noticeable colour in the images and gives the ordinary and extraordinary pencils a sufficient separation at the eye stop to permit the entire exclusion of one without the loss of any part of the other. If the prism were exactly at the focus and any part of the superfluous images were admitted the resulting secondary images would coincide with the others and thus lead to errors in observing. As it is owing to the construction of the instrument if the secondary images appeared at all they would do so only as additional stars near those under observation and too faint to produce any inconvenience.

Each observation consists of four comparisons after the first two the observer reverses the position of the star images in the field and also reverses the double image prism. The former precaution is necessary to eliminate a curious error depending on the relative position of the images which may amount to several tenths of a magnitude. Errors of this kind affect *all* estimates of the relative brightness of two stars in the same field, as has been repeatedly shown a striking instance is given by A. W. Roberts of Lovedale, South Africa (*Mon. Not. R.A.S.* 1897) who found

that his estimations of the brightness of variable stars required a correction depending on the position angle of the comparison star and ranging over nearly two magnitudes. In the Harvard work on the brighter stars the magnitude of the pole star was provisionally assumed to be 2.0 at the pole. Each observation had to be corrected for the effect of atmospheric absorption the coefficient for which was obtained from observations of circum-polars at upper and lower culminations. The provisional magnitudes thus obtained were finally corrected by a constant chosen so as to make the mean magnitude of the circum-polars equal to the mean magnitude of the same stars as given in the B.D.

Other types of photometer are Zollner's (*Photometrische Untersuchung* 1881) in which an artificial star is taken as the standard of comparison and Pritchard's in which the images of stars are viewed through a wedge and the wedge reading at which the star is extinguished noted.

The comparison of different catalogues of visual magnitudes reveals small systematic differences which arise out of the difficulties of estimating when two stars of different colour are equal in apparent intensity. The observation is complicated by what is known as the Purkinje phenomenon. If a blue source of light and a red source appear equally bright to the eye and if the intensity of each be diminished in the same ratio they will no longer seem equally bright the blue appearing the brighter. From this cause magnitudes observed with meridian photometers of different aperture will differ slightly. It becomes obvious that visual magnitudes ought to be referred to some standard instrument and possibly to some standard observer and it is difficulties such as these which are at the present time leading to the replacement of visual magnitude by what are known as photo-visual magnitudes.

#### PHOTOGRAPHIC PHOTOMETRY

Here we are dealing with a problem which differs considerably in detail from the visual procedure. We can no longer vary the light of a star by some device such as a Nicol prism until it is equal in brightness to a standard. But on a plate which has been exposed to a field of stars we can at any rate arrange the stars in order of brightness by measuring the diameters of the images or by estimating their degrees of blackness and we are then faced with the task of finding a means of relating our measures of blackness or of diameter to the true photometric scale defined as above.

Two principal methods have been employed the in focus method and the out of focus method. In the in focus method a field of stars is photographed twice on the same plate the intensity of the light being reduced in some known ratio for the second exposure. This can be effected by stopping down the aperture of the telescope by a given amount. The plate is placed in the usual position that is in the focal plane of the object glass or mirror. For each star we then have two images on the plate whose difference in magnitude is known. Now suppose we measure the photographic effect of each image in some way and denote the measure by  $D$ . A simple measure of photographic effect is the diameter of the image in which case  $D$  is the measured diameter. Suppose  $D_1$  and  $D_2$  be the measures on the two images of the same star. The difference of magnitude between these two images depends only on the ratio in which the aperture has been stopped down and is consequently known. We thus get the magnitude difference corresponding to the difference of the measures  $D_1$  and  $D_2$ . In other words we are relating the scale of our measures of photographic effect to the magnitude scale and we thus have a means of converting the measures into magnitudes and of obtaining the relative magnitudes of all the stars on the plate.

The principle of the method is as follows. Select a sequence of stars on the plate such that the diameter (or any other measure of photographic effect that may be adopted) of the fainter image of any member of the sequence is equal to the diameter of the brighter image of the next succeeding member. We then have a sequence of stars each member of which differs in magnitude from the following member by a known amount. In other words,

The first method is to use a wire grating of known spacing and to determine the wavelength of the light by measuring the angle of diffraction. This has been done by many observers and the results are in good agreement. The second method is to use a grating of known spacing and to determine the wavelength of the light by measuring the angle of diffraction. This has been done by many observers and the results are in good agreement. The third method is to use a grating of known spacing and to determine the wavelength of the light by measuring the angle of diffraction. This has been done by many observers and the results are in good agreement.

At Harvard the out of focus method has been used. In this case a series of exposures are made and for each exposure the plate is placed at a certain distance from the focus. Each star is now represented by a blackened patch on the plate instead of by the usual image and the density of the silver deposited in each patch is measured by comparison with a graduated wedge. In the case of the different exposures to the same star at different distances from the focus the relative quantities of light falling upon unit area of the plate are determined from straightforward geometry and the relation between the measured density and the magnitude scale thus determined (*Harvard Annals* vol. 59). It may be remarked that the out of focus method lends itself readily to the determination of the magnitudes of planets. For the purpose of determining the magnitudes of the sun and moon a pin hole camera was used by the Harvard observers and they obtained  $-25.83$  m for the photographic magnitude of the sun and  $-11.0$  m for that of the full moon (*Harvard Annals* vol. 59).

In recent years a great deal of care has been lavished upon the determination of the magnitudes of a sequence of stars extending down to the 20th magnitude and situated at the North Pole of the sky. This having been done the magnitudes of stars in any other part of the northern sky can be obtained by photographing the field and the pole on the same plate and with the same exposure. In order to eliminate atmospheric absorption the exposures should be made at the same altitude. Measures (say of diameter) can then be made of all the stars in each field and the measures calibrated from the determined magnitudes of the Polar sequence. Several secondary sequences have been determined in this way in various parts of the sky and the work is being pushed into the southern hemisphere.

**Colour indices and Standardization.**—The visual and photographic magnitudes are not necessarily the same. A red star for example may affect the eye strongly but its effect on an ordinary photographic plate which is chiefly sensitive to blue light may be small. The difference between the photographic and visual magnitudes of a star (which in extreme cases may amount to  $1\frac{1}{2}$  magnitude) reckoned in the sense photographic minus visual is called its colour index. However a little consideration will show that photographic magnitudes determined with different instruments (or different plates) will differ from

[illegible]

W. M. W. R. D. S. ... method of measuring colour indices ... H. ... colour indices ... blue and yellow ... size ... comparison with colour indices ... method has the advantage of determining the colour directly in each of the diffracting two separate magnitudes of determination. A further direct measure of colour is provided by the effective photographic wave length of a star. This may be defined as the wave length of the light from the star which produces the maximum effect on a photographic plate. It is greater for the red stars than for the blue and may be determined by placing a clear echelette grating over the aperture and then measuring the distance on the plate between the central image of a star and the most intense part of the lateral image produced by diffraction (*Mount's Notices* R 45 8 1911). Effective wave lengths having been determined they can be calibrated by comparison with colour indices.

**Photovisual Magnitudes.**—Just as different photographic determinations made by visual observers using different instruments obtain different results. There is also the complication arising from the Purkinje effect. For this reason attempts have been made of recent years to replace visual determinations by photographic ones made on colour sensitive plates through yellow screens. The resulting magnitudes are called photovisual magnitudes. They are roughly the same as the visual ones at any rate for the brighter stars, and lend themselves readily to standardization. Photovisual magnitudes have been determined at Mt. Wilson for the stars of the polar sequence. When compared with the Harvard visual results they show differences depending on colour which become more pronounced for the fainter stars, and may amount to as much as three tenths of a magnitude for red stars of the 1<sup>st</sup> magnitude.

**Spectro photometry**—It has been long recognized that the colour index of a star bears a relation to its surface temperature—the bluest stars being the hottest—and it is immediately suggested that the temperatures of the stars might be calculated from colour index data. This would be possible if the visual and photographic magnitudes referred to definite wave lengths instead as is actually the case of being results integrated over a certain range of spectrum. Consequently the satisfactory determination of what are known as effective temperatures can only be obtained by spreading out the light into spectra and confining the photometric measurements to certain definite wave lengths.

The effective temperature of a star may be defined for the present purpose as the temperature of a full radiator or black body for which the distribution of the energy in the spectrum most closely fits the observed distribution in the stellar spectrum. It is assumed that if as is usual measurements are confined to those spectral regions which are free from absorption lines the stellar distribution of energy is very nearly that of a black body and this is probably the case. The principle of the method may be stated thus. If for two stars the ratio of the light reaching us be measured for two separate wave lengths and if the effective temperature of one of them which is thus regarded as a standard star be known then the effective temperature of the other can be calculated. The problem is thus reduced to determining this ratio for two separate wave lengths or which comes to the same thing the difference of magnitude for the two wave lengths and

of the actual wave length and the difference between the actual and the effective wave length is the difference between the actual and the effective wave length. The object of the experiment is to determine what is the effective wave length in the blue and the red region of the spectrum. The effective temperature of the standard star can be known the effective temperatures of any others can be derived. The standard star need not be an actual star but an artificial source of light whose effective temperature can be determined in the laboratory.

It is on the line that research has been pursued at Potsdam, Edinburgh, Victoria, Greenwich and at other observatories. The work is still in its infancy and it is impossible to go into details here. With the exception of Potsdam, photographic methods are employed and one method is to measure the densities of the silver deposited in the spectra with some form of microphotometer. It then remains to relate the measures of density to the absolute photometric scale just as in the case of ordinary photometry. A graded series of images in light of the requisite wave lengths must be imposed on the plate and the measure of density thus calibrated. In the case of the visual work carried out at Potsdam the spectra were compared at each wave length with a Nicol prism photometer in a manner analogous to the Harvard visual photometry. The results that have been so far obtained are not altogether accordant and are subject to revision. The available observational data have been summarized by A. Brill (*Astronomische Nachrichten* 5539, 1918) who has given a table connecting spectral types and effective temperatures. According to this table the mean effective temperatures of stars of type B0 is 20800° Absolute. For type A0 the effective temperature is 13000° A and for type G0 (the solar type) it is 6050° A for the giants and 6240° A for the dwarfs. For the very red stars of type M0 Brill gives 3000° A and 3420° A for the giants and dwarfs respectively.

A very recent development is the determination by photometric methods of the integrated intensities of absorption lines, i.e. the ratio of the total amount of light absorbed in a line to the amount of light per unit of wave length in the neighbouring continuous spectrum. Some very promising work on these lines has been carried out at Harvard and it is probable that it will be developed rapidly in the immediate future. (W. M. H. G.)

#### PHOTON *see* COMPTON EFFECT

**PHOTOPERIODISM**, the term employed to designate the response of organisms to length of day with special reference to plants. Its possible application to animal life has not yet been adequately investigated though there is some evidence of its connection with bird migration. So far as known at present, sun light may affect plant growth in three ways in virtue of its composition including visible and invisible radiation in virtue of its intensity and its daily durations.

It has been found that for the sake of convenience plants may be considered to fall into three great groups depending upon the initiation of sexual reproductive expression and flowering in response to different day lengths. In one group termed the short day plants, day lengths of 12 hours or less are most favourable to the initiation of sexual reproduction. In a second group the long day plants, lengths of day in excess of 12 hours amounting in some instances to continuous illumination are most favourable for reproduction and flowering. A third group includes plants which attain sexual expression independently of any particular length of day. Such plants have been called indeterminate types, because they show no distinctive flowering response to either long or short days.

By the use of appropriate dark, ventilated chambers, or houses in which plants may be placed cutting off the early morning and later afternoon light of the long days of summer, it has been found practical to study the behaviour of plants as affected by daylight exposures much shorter than the normal. During the short days of winter, greenhouses suitably heated have been used, with electric illumination afforded the plants at sunset to increase the daily illumination periods to the desired degree. The behaviour of responsive plants has been consistent under the two

condition according as they are normally long day short day or indeterminate types of plants. *Poinsettia* is an example of a typical long day plant because the initiation of reproduction does not take place until the seasonal day length has fallen below 12 hours. Buckwheat is an indeterminate type of plant and *Oswegoto* bee balm (*Monarda didyma*) a garden ornamental demonstrates the long midsummer days for flowering.

The distinctive response of the different species of plants appears to have much to do with their normal ranges in many instances at least and is one of the factors in the environmental complex which must also be considered in any study of natural distribution. Likewise the geographical limits of some of our cultivated crops probably depend to a greater or less extent upon this factor. Bilo soy beans for instance a crop fruiting successfully in the Gulf States cannot be grown for seed in the Washington region (latitude 39°) because they do not flower until the September length of day is reached. As a result unfavourable temperatures with frost ensue and kill the plants while the pods are still immature.

As originally defined photoperiodism refers to the normal 24 hour period of time a constant condition which holds everywhere on the earth except at the poles. Breaking the normal daily duration of light during the long days of summer with a period of darkness of one to several hours in the middle of the day does not appear to produce any fundamental effect upon the normal reproductive development of typical long or short day plants.

In addition to its effects upon sexual reproduction day length is known to modify composition, growth and development of plants in various ways including tuberization, branching habit, root and rhizome development, stature, dormancy, leaf fall, senescence, rejuvenescence and cleistogamy.

In any analysis of plant behaviour either in the field or in the laboratory the factor of photoperiodism must be considered as operative in the environmental complex. Just as plants are known to have their specific requirements with respect to temperature, moisture, light intensity etc. it is known that they have definite length of day requirement for promoting the different phases of vegetative expression of flowering and fruiting. The character and extent of these expressions, the seasonal behaviour, stature, longevity etc. may be more a matter of response to length of day than anything else. This principle has probably been unconsciously applied in the agricultural operations of man with his various economic and ornamental plants just as the requirements of temperature, light intensity, soil, moisture etc. have been met. Definite recognition of the principle will unquestionably aid greatly in a more intelligent interpretation of plant behaviour and prove a factor of no small importance in the successful introduction of plants from one region into another. The phenomena of photoperiodism were brought to the attention of the scientific world in 1920 by workers in the U.S. Department of Agriculture.

(W. W. G. H. A. A.)

**PHOTOSPHERE** of the sun, the layer from which most of the sun's light is emitted which reaches us directly, i.e. without absorption and re-emission. The sun is a globe of gas with no sharply defined surface and we look down into it through absorbing layers of very low density. The photosphere may be regarded as the layer which is the limit to which we can see into the interior. (*See* SUN)

**PHRAATES** (p hrah ah tas) (PHRAHATES) the name of five Parthian kings.

1 PHRAATES I, son of Priapatrus, reigned c. 175-170 B.C. He subdued the Mardi & mountainous tribe in the Elburz (Justin xli. 5. Isid. Charac. 7). He died young and appointed as his successor not one of his sons but his brother Mithradates I (Justin xli. 5).

2 PHRAATES II, son of Mithradates I, the conqueror of Babylonia, reigned 138-127. He was attacked in 130 by Antiochus VII. Sidetes who, however, in 129 was defeated and killed in a great battle in Media, which ended the Seleucid rule east of the Euphrates. (*See* SELEUCID DYNASTY) Meanwhile the

In the following list the localities are appended to the names, which are mostly the inventions of Spurzheim. Gall's names are placed in brackets. For topography, Broca's names are adopted.

**Propensities.**—I. Amativeness (*Instinct de la génération*).

7 (1) below theinion

Phreprocrates (*Amour de la propreté*) median on the squamous suture

Cor e a n e below the obelion and o e h lambda

4 Adhe (1) over the late 2 rea o the lamb

Cor thit eric s (*Insinct d l d f i s*) who e he asterion

6 Dis ru i re (*It i c can s e r*) above the ear me tus

6 Almen vere over the tempo l muscle and above the ear

7 Secretiveness (*Ruse Finesse*) the posterior part of the squamous suture

8 Acquisitiveness (*Sentiment de la propriété*) on the upper edge of the front half of the squamous suture

9 Constructiveness (*Sens de mécanique*) on the stephanion

The organ of Vitativeness or love of life is supposed by Combe to be seated at the base of the skull

**Lower Sentiments.**—10 Self esteem (*Orgueil fierte*) at and immediately over the obelion

11 Love of Approbation (*Vanité*) outside the obelion

12 Cautiousness (*Circonspection*) on the parietal eminence

**Superior Sentiments.**—13 Benevolence (*Bonté*) on the middle of the frontal bone in front of the coronal suture

14 Veneration (*Sentiment religieux*) median at the bregma

15 Conscientiousness Believingness (Forster) unknown to Gall recognized by Spurzheim usually from its deficiency and placed between the last and the parietal eminence

16 Firmness (*Fermeté*) median on the sagittal suture from behind the bregma to the front of the obelion

17 Hope not regarded as primary by Gall who believed hope to be akin to desire and a function of every faculty which desires and left this territory unallocated

18 Wonder said to be large in vision seers and many psychic researchers A second similar organ placed between this and the next is called Mysterizingness by Forster and is said to be the

et of belief in ghosts and in the supernatural

9 Ideality (*Poesie*) noted by Gall from its prominence in the bus of poets said to be the part touched by the hand when composing poetry

10 Wit (*Esprit caustique*) the frontal eminence

11 Imitation (*Faculté d'imiter*) disposition to mimicry placed between Benevolence and Wonder

**Perceptive Faculties.**—2 Individuality over the frontal sinus in the middle line

Form (*Mémoire des personnes*) capacity of recognizing faces gives a wide interval between the eyes

4 Size over the trochlea at the orbital edge

5 Weight outside the last on the orbital edge and like it over the frontal sinus

6 Colour also on the orbital edge external to the last

7 Locality (*Sens de localité*) placed above Individuality on each side and corresponding to the upper part of the frontal sinus and to the region immediately above it

8 Number on the external angular process of the frontal bone

29 Order internal to the last

30 Eventuality (*Mémoire des choses*) the median projection above the glabella

31 Time below the frontal eminence and a little in front of the temporal crest

3 Ture (*Sens des rapports des tons*) on the foremost part of the temporal muscle

33 Language (*Sens des mots*) behind the eye

**Reflective Faculties.**—34 Comparison (*Sagacité comparative*) median at the top of the bare region of the forehead

35 Causality (*Esprit métaphysique*) the eminence on each side of Comparison

**Anatomical and Physiological Considerations.**—The teaching of anatomy with regard to phrenology may be summarized thus (1) the rate of growth of brain is concurrent with the rate of development of mental faculty (2) there is some degree of structural differentiation as there are varying rates of development of different parts of the cerebral surface (3) there is no accordance between the regions of Gall and Spurzheim and definite areas of cerebral surface

That the brain is the organ of the mind is now universally received While it is probable that certain molecular changes in the grey matter are antecedents or concomitants of mental phenomena the precise nature of these processes to what extent they take place or how they vary among themselves have not as yet been determined experimentally the occurrence of the change can only be demonstrated by some such coarse method as the altered pulsation of the carotid arteries the increase of the temperature of the head the abstraction during brain action of blood from other organs as shown by the plethysmograph or the formation of lecithin and other products of metabolism in brain substance

**Psychological Aspect.**—There is a large weight of evidence in favour of the existence of some form of localization of function So little is known of the physical changes which underlie psychological phenomena or indeed of the succession of the psychological processes themselves that we cannot as yet judge as to the nature of the mechanism of these centres So much of the psychic work of the individual life consists in the interpretation of sensations and the translation of these into motions that there are strong a priori grounds for expecting to find that much of the material of the nerve centres is occupied with this kind of work but in the present conflict of experimental evidence it is safer to suspend judgment That these local areas are not centres in the sense of being indispensable parts of their respective motor apparatus is clear as the function abolished by ablation of a part returns though tardily so that whatever superintendence the removed region exercised apparently becomes assumed by another part of the brain Experimental physiology and pathology by suggesting other functions for parts of the brain surface are thus subversive of many details of the phrenology of Gall and Spurzheim

The fundamental hypothesis which underlies phrenology as a

### Adverse Conclusions

I have seen a number of cases of this kind. In some of them the brain was found to be compressed by the skull, and in some it was found to be compressed by the dura mater. In some cases the brain was found to be compressed by the skull, and in some it was found to be compressed by the dura mater. In some cases the brain was found to be compressed by the skull, and in some it was found to be compressed by the dura mater.

All these and other cogent reasons of a like kind whose force can be estimated by those accustomed to deal with the component soft parts of the head should lead phrenologists to be careful in predicting relative brain development from skull shape. Psychology, physiology and experience alike contribute to discredit the practical working of the system and to show how worthless the so called diagnoses of character really are. Its application by those who are its votaries is seldom worse than amusing but it is capable of doing positive social harm as in its proposed application to the discrimination or selection of servants and other subordinate officials.

**PHRYGIA**, the name of a large district of Asia Minor in ancient times derived from a people whom the Greeks called Φρύγες i.e. freemen" Taken at its widest extent, Phrygia comprised the whole north west and centre of Asia Minor as far as the ~~ever~~ Halys and the southern mountain-edge of the penin-

The region of the Sangarius and the Aegean Bu-  
 for the first time to an inland district  
 from the coast of the Propontis, and from the  
 all the way to the Sangarius and

 considerable  
 in the district of Chironia  
 in the neighborhood of Iconium but the  
 of Doornik a white stone  
 streated with iron oxide

The principal line of communications across Phrygia was a route which rose steeply out of the Hermus valley and traversed the entire length of the plateau in a somewhat irregular line proceeding first in a northerly direction to Dorylaeum thence eastward past Corium and Ancia to the old Hittite capital at Boghaz Keu. This road even usually termed part of the Royal road by which the Achaemenid kings of Persia connected Sardes and the Aegean seaboard with their capital at Susa. It appears at all times to have served a military and administrative rather than a commercial purpose. The southern edge of Phrygia was crossed by another trunk road which ascended the valley of the Lycus (a tributary of the Maeander) to Apameia (Laenae) and thence led to Iconium and across Mt. Taurus into Syria. This route was much used by the Seleucid kings of Syria and by the Romans and was probably at every period the chief line for commercial traffic to the Aegean sea. The scenery of Phrygia is generally monotonous. Even the mountainous districts rarely show striking features or boldness of character.

**The Phrygian Immigration**—It may be taken for granted that the population of Phrygia always contained a large element of that indigenous Asiatic stock whose survival to the present day has been noted by modern travellers. The persistence of this element in ancient times is indicated by the continued prevalence of native Asiatic cults in Phrygia (*See* p. 833). But the Phrygians properly so called were an immigrant folk. According to Greek tradition they entered Asia Minor from Thrace or Macedonia and this tradition is confirmed by the fact that their language was certainly Indo-European.

For the date of the Phrygian immigration the best evidence is found in Homer who represents the Phrygians as rendering aid to King Priam at the siege of Troy in return for assistance which he had given to them in their wars against the Amazons (=the Hittites<sup>2</sup>) on the banks of the Sangarius. This story indicates that the Phrygians had entered Asia Minor some time before 1200 B.C. A date not later than 1500 B.C. has been inferred from the furniture of certain burial mounds in north western Asia Minor which resemble the contents of Macedonian tumuli of the early second or late third millennium.

It would appear from Homer that the incoming Phrygians made their principal settlement in the Sangarius valley. Their chief surviving monuments are also found in this valley (at Gordium) and on the adjacent plateau to the south west of the Sangarius. But it is probable that about 1000 B.C. all the northern and central parts of Asia Minor had come under Phrygian occupation. The extension of Phrygian power to the western seaboard of Asia Minor may be inferred from a somewhat enigmatic Greek tradition that in the 9th century B.C. they exercised a 'thalasocracy' or 'lordship of the seas' in Aegean waters and from the abundance of Phrygian remains on Mt. Sipylus in the lower Hermus valley. The description of Sinope as a 'Phrygian' town indicates a Phrygian settlement along the Black sea. Another Greek tradition that the Armenians were an offshoot of the Phrygian stock, is supported by the resemblance between the

PHRYNÉ, a famous courtesan of the 4th century B.C. Her story is told in the *Symposium* of Plato. She was a native of Phrygia and was famous for her beauty and her wit. She was the lover of the philosopher Plato and was the mother of his son. She was also the lover of the poet Phrynichus. She was a very famous courtesan and was the most famous of her kind in the world. She was a very beautiful woman and was very famous for her beauty. She was the lover of the philosopher Plato and was the mother of his son. She was also the lover of the poet Phrynichus. She was a very famous courtesan and was the most famous of her kind in the world. She was a very beautiful woman and was very famous for her beauty. She was the lover of the philosopher Plato and was the mother of his son. She was also the lover of the poet Phrynichus.

The alphabet used by the Phrygians bears a close relation to either of the characters of the Phoenician but is exact relation to either of the characters has not been determined. It is only represented by a few examples all the later inscriptions from Phrygia are in Greek or Latin character. The Phrygian tongue which may best be traced in the fairly numerous text (mostly epigrams) of the early century A.D. is akin to Armenian. In the period of Greek and Roman rule it gave way to Greek in the towns but on the country side it remained in use until the 5th century A.D. (See ASIATIC LANGUAGES.)

**Religion**—The religion of Phrygia was plainly a composite product. The Phrygian immigrant of c. 1000 B.C. brought with them several typical Indo-European gods such as Pappas the equivalent of the Greek Zeus and Men a male moon deity. The god Sabazios who was usually equated by ancient writers with the Thracian Dionysus may be referred to the same group. But the gods of the Phrygian invaders were never able to displace the original Asiatic deities of whom the foremost were Cybele the Great Mother and Attis a youth who died untimely but in death retained his beauty of figure. This couple which had several parallel in the religions of the Near East evidently represented the generative force of nature and the vegetation that withers and blooms with each new season. The worship of these deities was highly orgiastic and their priests the so-called Galli carried their devotion to the point of self mutilation. The principal sanctuary of Cybele stood at Pessinus by Mt Dindymus in central Phrygia where a hierarchy of priests exercised theocratic rule over the inhabitants of the extensive temple estates. Not only did the cult of Cybele and Attis maintain itself against the religion of the Phrygian newcomers but it partially absorbed them. Nay more it more than held its own against the religions of Greece and Rome and it competed against these on European soil. The worship of Cybele spread to Greece in the 5th century B.C. in 404 B.C. it was officially established at Rome in the days of the Roman empire it was carried on the tide of oriental immigration into every part of Italy and penetrated the western provinces as far as the Rhineland and Britain. Thus the religion of Phrygia was its most distinctive contribution to ancient Mediterranean civilization. The influence of the native Asiatic religion may also be traced in the various heresies and especially the heresy of Montanus (himself a Phrygian) that arose in Phrygia after the spread of Christianity. Nevertheless the conversion of Phrygia to Christianity was remarkably early and complete. Christian inscriptions begin there in the 2nd century and are abundant in the third. In all probability the mass of the people had been converted by 300 and Eusebius is no doubt correct in saying that in one Phrygian city at that time every soul was a Christian.

**BIBLIOGRAPHY**—(a) *Topography and Monuments*—Recent records of exploration will be found in the numerous books and articles of Sir William Ramsay especially in his *Cities and Bishoprics of Phrygia* (1895-97) and in the *Journal of Hellenic Studies* (1882 ff.). The results of the German excavations at Gordium are set forth in Körte, *Gordium* (1904). **PHRYNICHUS** 1. Son of Polyphradmon and pupil of Theophrastus one of the earliest of the Greek tragedians. Some of the ancient indeed regarded him as the real founder of tragedy. He gained his first poetic victory in 480 B.C. His most famous play was the *Capture of Miletus*. The audience was moved to tears the poet was fined for reminding the Athenians of their misfortunes and it was decreed that no play on the subject should be produced again. In 466 Phrynichus was successful with the *Phoenissae* celebrating the victory of Salamis and especially the deeds of Themistocles who was choragus. Phrynichus is said to have died in Sicily. He introduced a separate actor as distinct from the leader of the chorus and thus laid the foundation of dialogue. But in his plays as in the early tragedies generally the dramatic element was subordinate to the chorus. According to Suidas Phrynichus first introduced female characters on the stage (played by men in masks) and made special use of the trochaic tetrameter.

Fragments in A. Nauck *Tragicorum graecorum fragmenta* (1887).

2. A poet of the Old Attic comedy and a contemporary of Aristophanes. His first comedy was exhibited in 490 B.C. He composed ten plays of which the *Solitary* (*Μονοτροπος*) was exhibited in 414 along with the *Birds* of Aristophanes and gained the third prize. The *Muses* carried off the second prize in 405. Aristophanes being first with the *Frogs* in which he accuses Phrynichus of employing vulgar tricks to raise a laugh of plagiarism and bad versification.

Fragments in T. Kock *Comicorum atticorum fragmenta* (1880).

3. PHRYNICHUS ARABUS a grammarian of Bithynia lived in the 2nd century A.D. According to Suidas he was the author of (1) an *Atticist* in two books (2) *Τυθεμένων συλλαβών* a collection of subjects for discussion (3) *Σοφιστικὴ Παρασκευή* or Sophistical Equipment. The work was learned but prolix and garrulous. A fragment contained in a Paris ms. was published by B. de Montfaucon and by I. Bekker in his *Anecdota graeca* (1814). Another work of Phrynichus not mentioned by Photius but perhaps identical with the *Atticist* mentioned by Suidas the *Selection* (*Ἐκλογή*) of *Attic Words and Phrases* is extant. It is a collection of current words and forms which deviated from the Old Attic standard and is interesting as illustrating the changes through which the Greek language had passed between the 4th century B.C. and the 2nd century A.D.

Editions of the *Ἐκλογή* with valuable notes have been published by C. A. Lobeck (1820) and W. G. Rutherford (1881). Lobeck devotes his attention chiefly to the later, Rutherford to the earlier usages.

**PHTHALIC ACIDS**, the name given to the three isomeric dicarboxylic acids  $\text{C}_6\text{H}_4(\text{COOH})_2$ , (1) ortho or phthalic acid (2) meta or isophthalic acid (3) para or terephthalic acid. The most important is the first as it forms the starting material in the production of many synthetic dyes and of the synthetic resin known as phthalate.

*Phthalic acid* was obtained by Laurent in 1836 by oxidizing naphthalene tetrachloride and believing it to be a naphthalene derivative he named it naphthalenic acid. Margnac showed Laurent's supposition to be incorrect upon which Laurent gave it its present name. It was formerly manufactured by oxidizing naphthalene tetrachloride (prepared from naphthalene potassium chlorate and hydrochloric acid) with nitric acid or by oxidizing the hydrocarbon with fuming sulphuric acid using mercury or mercuric sulphate as a catalyst (German pat. 91,000). These methods have been superseded by a catalytic process in which air and naphthalene vapour are passed over heated vanadium pentoxide; the yield is upwards of 80% of phthalic anhydride which is readily separated by fractional sublimation from unchanged naphthalene. Phthalic acid forms white crystals melting at 213° with decomposition into water and phthalic anhydride; the latter forms long white needles melting at 118° and boiling at 284°.

Phthalyl chloride  $\text{C}_6\text{H}_4(\text{COCl})_2$  or  $\text{C}_6\text{H}_4(\text{CCl})_2(\text{CO})_2\text{O}$  formed by heating the anhydride with phosphorus pentachloride is an oil solidifying at 0° and boiling at 175°. In some reactions it behaves as having the first formula in others as having the second. Phthalyl chloride with phosphorus pentachloride gives two phthalylene tetrachlorides, one melting at 88° and the other at 41°. They cannot be changed into one another and have been given the formulae  $\text{C}_6\text{H}_4(\text{CCl}_2)(\text{COCl})_2$  and  $\text{C}_6\text{H}_4(\text{CCl}_2)_2\text{O}$ .

*Isophthalic acid* is obtained by oxidizing meta xylene with chromic acid or by fusing potassium meta sulphobenzoate or meta bromobenzoate with potassium formate (terephthalic acid is also formed in the last case). It melts above 300° and dissolves in 1,800 parts of cold water and in 460 of boiling.

*Terephthalic acid* formed by oxidizing para derivatives of benzene or best by oxidizing caraway oil a mixture of cymene and cuminol with chromic acid is almost insoluble in water, alcohol and ether; it sublimes without melting when heated.

**PHTHISIS** (tisis) a name formerly given (like Consumption) to the disease of the lung now known as Tuberculosis (*q.v.*) from the wasting often observed. This wasting depends mainly upon secondary infection of tuberculous areas by pyogenic micrococci and is accompanied by much fever and profuse sweating. Modern tendency is to use the term phthisis only when implying the existence of this double infection.

**PHYFE, DUNCAN** (c. 1768–1854) American cabinet maker was born near Inverness, Scotland in 1768, came to the United States about 1783 and was apprenticed to a cabinet maker in Albany. He moved to New York city in 1790 where he opened a shop first in Broad Street later in what is now Fulton Street. He made chairs, tables, settees, sideboards and other furniture following his own adaptations of Sheraton and Adam styles and using chiefly mahogany. After 1800 he copied Empire styles. His best period was that in which he was under the influence of Sheraton. Most of the Phyfe furniture is characterized by excellent proportions, graceful curves, the use of reeding and brass ornamentation, the best known motifs being the acanthus leaf, the oak leaf and the lyre. Duncan Phyfe died in New York 1854.

**PHYLACTERY**, a term applied in Matt. xxiii. 5 to the *tefillin* of the Jews on the assumption that these were amulets (*φυλακτήρια*), against physical evil. *Teffilin* either from *teph* to attach or *teph* whence *teph* prayer are certain Pentateuchal texts which in accordance with Exod. xii. 16 and Deut. vi. 5–9 were to be worn as constant reminders of God during the daily avocations. Hence they were not used on Sabbaths and festivals as

on that day it was a reminder and the schools and markets were closed. The idea of such an outward sign is common. The modern habit of wearing a cross on a watch-chain may be compared. Romans had tablets for memoranda hanging from the wrists. Isaiah lv. 16 evidently denotes this custom. Possibly the origin is to be sought in tattooing. *Teffilin* are worn on the hand and head, the verses being enclosed in leather boxes fixed in position by leather thongs. The hand phylactery has one compartment in which the texts figure on one parchment; the head phylactery having four such compartments each with one text. The extracts are Ex. xiii. 1–10, 11–16, Deut. vi. 4–9, xi. 13–21.

**BIBLIOGRAPHY**—For further details illustrations and historical and critical view see *Jewish Encyclopedia* s.v. For the prayers and meditations see *S. S. N. S. Author's Daily Prayer Book* pp. 19–59. For certain Jewish objections see A. Asher's *Collected Writings* pp. 80–81 (1916 privately printed). Linked with *Teffilin* are the *Mezuza* (door text) and *Cytha* (ring). The former is a text containing Deut. vi. 4–9 rolled in a glass or metal tube on the right hand of each door so that everyone who enters or leaves shall think of God (see *Jewish Encyclopedia* Singer ed. cit. p. 292). The latter (see *Jewish Encyclopedia* s.v. *Lin*) is based on Numbers xv. 37–41 which ordains the knotted tassel as a mnemonic.

**PHYLE**, a mountain fortress on a pass leading from Athens into Boeotia on the south west end of Mt. Parnes famous for its occupation by Thrasybulus at the head of the Athenian exiles during the rule of the Thirty Tyrants in 404 B.C. Defending himself with the help of a snowstorm he succeeded by a night march in seizing Munychia.

**PHYLLITE**, in petrology a group of rocks which are in practically all cases metamorphosed argillaceous sediments consisting essentially of quartz, chlorite and muscovite and possessing a well marked parallel arrangement or schistosity so called from *Gr. φύλλον*, a leaf, probably because they yield leaf-like plates owing to their fissility. They form an intermediate term in the series of altered clays or shaly deposits between clay slates and mica schists. The clay slates have a very similar mineral constitution to the phyllites but are finer grained and are distinguished also by a very much better cleavage. In the phyllites also white mica (muscovite or sericite) is more abundant as a rule than in slate and its crystalline plates are larger; the abundance of mica gives these rocks a glossy sheen on the smooth planes of fissility.

A microscopical section of a typical phyllite shows green chlorite and colourless mica both in irregular plates disposed in parallel order with a greater or smaller amount of quartz which forms small lenticular grains elongated parallel to the foliation. Grains of iron oxide (magnetite and haematite) and black graphitic dust are very commonly present. Felspar is absent or scarce but some phyllites are characterized by the development of small rounded grains of albite often in considerable numbers. The minute needles of rutile so often seen in clay slates are not often met with in phyllites but this mineral forms small prisms which may be intergrown with black magnetite. At other times it occurs as networks of sagenite. Other phyllites contain carbonates (usually calcite but sometimes dolomite) in flat or spindle shaped crystals which often give evidence of crushing. Very tiny blue needles of tourmaline are by no means rare in phyllites though readily overlooked. Garnet occurs sometimes a good example of the garnetiferous phyllite being furnished by the whetstones of the Ardennes in which there are many small isotropic crystals of manganesian garnet. Hornblende often in branching feathery crystals is a less frequent accessory. In some phyllites a mineral of the chloritoid group makes its appearance; this may be ottrelite, sismondine or other varieties of chloritoid and occurs in large sub hexagonal plates showing complex twinning and lying across the foliation planes of the rock.

The structural variations presented are comparatively few. The most finely crystalline specimens have generally the most perfect parallel arrangement of their constituents. The foliation is generally flat or linear but in some rocks is undulose or crumpled. From the imperfection of their cleavage phyllites are rarely suitable for roofing materials; their softness renders them valueless as road stones but they are not uncommonly employed as inferior building materials. They are exceedingly common in all parts of the world where metamorphic rocks occur as in the

## PHYLLIOXERA,

FIG 1—ROOT INHABITING FORM OF THE PHYLLIOXERA WITH ITS PROBOCIS INSERTED INTO TISSUE OF ROOT OF VINE

The root-inhabiting form of the phylloxera was first discovered in France in 1880. It was imported into Europe between 1880 and 1886 when it was introduced into the United States for grafting purposes and had reached most every vine-growing country in the world. The root-inhabiting European record was in England in 1886. Soon afterwards it was identified in France where it rapidly spread through the vineyards of that country. By 1888 it had extended to most other European grape-producing countries and had reached Algeria, Australia, and the Cape. It was first discovered in California in 1880 but there is evidence that it was present in that State from about 1883 being introduced along with American vines from east of the Rocky Mountains. It was the advent of the highly susceptible European grape that led to the phylloxera becoming a pest in the Californian vineyards. The presence of this insect is manifested by the vine being stunted and bearing smaller and fewer leaves. When the disease is advanced the leaves are discoloured and galls are present on their under surface. These galls are wrinkled and hairy and their cavity communicates by means of an opening upon the upper surface of the leaf. If the root be examined numerous knotty swellings are found upon the smaller rootlets at first yellowish in colour and finally assume a brown or black colour and become rotten. At the same time the grapes themselves are retarded in their growth and their skins become wrinkled. The damage wrought by the phylloxera is occasioned by the extraction of the sap by means of the piercing suctorial mouth parts of this insect and the subsequent deformation of the plant that is brought about. Millions of acres of vineyards have been destroyed by this pest and when at its worst in France it is stated to have ruined 500,000 acres which represented an annual loss in wine products of £50,000,000.

The complete life history of phylloxera is briefly as follows. A single egg is laid by the fertilized female on the bark of the vine where it passes the winter. It hatches in spring into a wingless female or *fundatrix* which creeping into an opening bud of the vine forms a gall on the young leaf and lays therein a number of eggs. The latter develop into further wingless forms or *gallicolae* which multiply rapidly and produce new generations of gall formers on the leaves. Among their progeny there appear later in the season wingless females of different behaviour the *radicolae* (fig 1) which pass to the roots. The *radicolae* continue reproducing generations of their own kind but among them winged migrants (fig 2) eventually appear. These occur from July until October and fly to other vines where they lay two kinds of eggs—small male producing eggs and large female producing

FIG 2—WINGED MIGRANT FEMALE  
Hatched from the egg of the phylloxera this form flies to other vines where it lays as then generally egg of two kinds

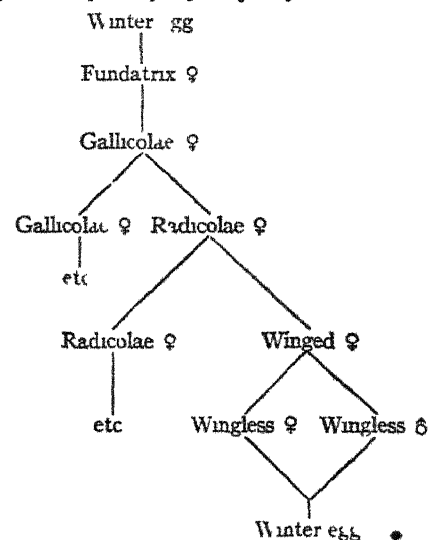

FIG 3—MALE AND FEMALE FROM EGGS LAID BY WINGED MIGRANT FEMALE

usually fail to develop in the absence of certain American vine and the gallicolae generations are consequently rare. Reproduction and spread are brought about by the *radicolae* many of which hibernate and continue multiplying in spring. According to the German authority Bocrner there is a race of phylloxera found in Lorraine which produces galls on European vine but not on most American varieties and he has given this Lorraine race the distinctive name of *perastatrix*.

### Scheme of the complete life cycle of Phylloxera

Many control measures have been suggested against the phylloxera but few have been generally adopted in practice. The enforcement of quarantine regulations precluding the distribution of rooted vines from infested areas is important. The utilization of vine stocks less susceptible to the root feeding form of the insect is generally recognized. Varieties of American grapes such as *Vitis riparia*, *V. rupestris*, *V. berlandieri* and their hybrids are not seriously injured by the *radicolae* and by growing these varieties or using them as stocks upon which the susceptible European varieties have been grafted injuries by the pest have been greatly reduced. In certain cases the injection of carbon bisulphide into the soil to kill the root form of the insect has been profitable. The flooding of infested vineyards has been a recog-

Vienna.

**PHYSICAL CULTURE** is the development of the body by  
exercise to promote and maintain good health or to correct defect  
or weakness of the body. Benefit to the body is the main object  
and recreation derived therefrom is incidental. Physical culture  
in its simplest form is taking exercise such as getting up exercises  
or calisthenics. The use of equipment—dumbbells, bands or  
weight machine—though not necessary, adds interest and variety  
to the exercises.

**Development**—The value of exercise to promote health and  
physical strength has probably always been recognized by man.  
In ancient and mediaeval times building up of the body was  
principally for purpose of war or in ancient Greece pre-  
liminary training for sports. Systematic physical culture first  
appeared during the last part of the 18th century in Germany.  
In 1774 Basedow founded at Dessau a school in which running  
walking, riding, and manual labour were prescribed as exercise  
for the student. In 1785 Guts Muth started a system of gym-  
nastics in a school near Gotha and in 1795 published a book  
*Gymnastics for the Young*. At about the same time Nachtigall  
in Denmark and Lin in Sweden were introducing physical  
training in those countries.

To Professor Ludwig Jahn of Germany should probably go the  
greatest credit for organizing physical training on a broad scale  
for the benefit of all the people of the country. Under the direc-  
tion of Jahn boys, youths and men of all classes of society took  
part in exercise for physical development throughout Germany  
(about 1810). Even with Jahn the idea was physical culture  
with the ultimate object of physically strengthening the man  
power of Germany for war. Physical culture first appeared in the  
United States and England about 1825 and probably in other  
European countries at about the same time. It developed slowly  
between 1850 and 1875. Since 1875 due to the rapid growth of  
the machine, mechanical transportation and labour saving de-  
vices the occupations of millions of adults have changed from  
manual labour to office work, the play of children has been re-  
stricted in large densely populated cities, thus the necessity for  
and practice of physical culture has grown rapidly.

**General Rules**—From 10 to 15 minutes daily is sufficient for  
physical culture exercises, preferably in the middle of the morning  
or in the afternoon. Exercise immediately before or after a meal  
should be avoided. Children should be given exercises under the  
supervision of teachers or parents. If the exercise must be taken  
before breakfast it should be immediately after rising and be  
followed by a warm bath and dressing leisurely. If the daily bath  
is taken at night the exercises should precede the bath. The air  
in the room should be fresh but not chillingly cold. Clothing  
should be light and loose. All parts of the body should be exercised  
during each period even when the object is to strengthen a par-  
ticular part but no part should be given more than two exercises  
in succession. For example take an arm exercise, a trunk exercise,  
a leg exercise etc. following some system of rotation. After an  
exercise that causes muscular strain take one that loosens the  
muscles. Take the breathing exercise at the middle and end of the  
period. The exercises may be made harder by going to full  
positions, increasing the cadence or number of repetitions and  
by the use of equipment. They may be made easier by going to  
quarter positions and executing slowly. For those who are old or  
weak the milder exercises should be selected and regulated to  
result in good circulation of the blood and loosening up and

loosening the muscles without exhaustion.

**Attention**—Start the exercises from the position of attention  
feet on the same line, toes turned out equally at  
about 45 degrees, resting on the balls of the feet, legs straight  
but not in hips level, stomach drawn in, chest raised, back  
straight, shoulders back and sloping equally, neck and head  
vertical, chin raised, body and mind alert. In moving the shoul-  
der back keep the stomach drawn in, otherwise a swayed back  
position will result. Standing with the back to a flat wall and  
a finger on the back touch it from head to heel will  
indicate how the stomach must be drawn in to make the back  
straight. Repeat each exercise from 5 to 15 times. Words in  
parentheses below indicate parts of the body that will be bene-  
fited.

**Exercises Arms Sideward**—horizontal, palms down, fingers  
extended and joined, arms stretched. (1) Close fists. (2) spread  
fingers to fullest extent. Repeat ten times. Variations: Move  
wrists up and down, or right and left, or with a rotary motion.  
(Forearms, wrist, biceps).

**Arms to Thrust**—forearms horizontal and parallel at waist,  
elbows back, fists closed, back of hands down. (1) Thrust arms  
to front, horizontal, palms down. (2) swing sideward, palms up,  
forcing shoulders back and chest out. (3) return to front position.  
(4) return to thrust. (Chest, shoulders). Variation: At 2 swing  
arms upward.

**Arms Sideward Upward**—vertical, parallel, palms facing. (1)  
Bend trunk to right side. (2) recover starting position. (3) bend  
trunk to left. (4) recover. (Trunk, side and back muscles).  
Variations: Bend trunk 30° forward and backward on 1 and 3.  
Bend trunk forward and circle right, back left and forward.

**Hands on Hips**—thumbs to rear, tips of fingers on point of hip.  
(1) Quarter bend, knees spreading them and lowering trunk in  
its erect position as far as possible without raising heels. (2)  
recover. (Leg muscles and joints, balance). Variations: Half  
bend—heels off floor, or full bend—sitting on heels in all cases  
body erect.

**Hands on Shoulders**—tips of fingers touching shoulder, elbows  
to sides and pressed back, upper arm horizontal. (1) Rise on toes,  
stretching body upward, at same time extend arms to side, hori-  
zontal, palms up. (2) recover. (Toes, calves, arms). Variations:  
Extend arms forward or upward or to the three positions in  
rotation.

**Hands on Hips**—(1) Bend neck forward, chin in, stretching back  
of neck. (2) recover. (3) bend neck backward. (4) recover.  
Variations: Bend neck to sides or bend forward and circle head  
right, back left, forward.

**Arms Sideward Upward**—lock thumbs, palms to front. (1) Full  
bend trunk forward, touching floor, knees straight. (2) recover.  
(3) bend trunk backward. (4) recover. (Stomach and back  
muscles). Variations: Spread feet about 18 in. and swing hands  
down and back between legs or twist trunk as it bends forward  
and swing arms to side of legs and backward.

**Hop to Side Straddle**—feet spread about 24 in., landing on toes  
and raising arms sideward upward. (2) recover, attention on toes.  
Execute in fast cadence, loosening up all muscles of body.

**Lunge forward** with right foot 30 to 40 in., right knee bent,  
raising arms to side, horizontal, palms up, upper body erect. (2)  
bend trunk forward, clasping right knee with both arms. (3)  
recover first position. (4) recover, attention. Repeat lunging with  
left foot. (General exercise, arms, trunk and legs). Variations:  
Lunge to sides and on 2 twist as well as bend the trunk so as to  
clasp the knee.

**Bend to squatting position**, hands on floor between the feet,  
knees spread. (2) extend legs backward, feet together, toes on  
floor, body straight, supported only on toes and straight arms.  
(3) recover, squatting position. (4) recover, attention. (General  
exercise, arms, shoulders, trunk, back, legs). Variations: Extend  
one leg back at a time, alternating, or both legs back and at (3)  
spread feet 30 to 40 in., at (4) bring feet together. (5) recover,  
squatting position. (6) recover, attention.

**Lie on Back**—hands at sides, palms on floor; (1) Raise right leg  
to vertical, knee straight, toes pointed upward. (2) lower. (3)

Man's migrations over the globe and his ability to sustain himself under diverse and adverse conditions have depended largely on animal life. With the camel or horse man can live in the desert. With sheep he can establish himself in regions of high elevation or sparse vegetation. With the presence of wild birds and a few dogs he can inhabit the frigid zones. Under the more

and in the United States, the number of animals has increased. For such a long time, the number of animals has been increasing. The number of animals has been increasing. The number of animals has been increasing.

In the case of the United States, the number of animals has been increasing. The number of animals has been increasing. The number of animals has been increasing. The number of animals has been increasing.

**Live Stock Production**—In the age old struggle for the survival of the fittest, certain types of animal life have proved to be especially well adapted to man's requirements. The che has preserved improved and protected until their production has become a major part of the world's agriculture. It is important to bear in mind that crop production and stock raising are closely allied enterprises. Inasmuch as animals consume most crops that are not utilized by man directly. Moreover, land that is too rough for cultivation may support vast herds of cattle, sheep and goats. (See *Vegetation* below.) Thus live stock serves as a useful balance wheel in the mechanism of human nutrition. Famine rarely occurs in countries where live stock is abundant.

As in the production of other commodities, however, a great number of economic factors are involved. These influence the extent of animal breeding and feeding operations, thus determining the number of animals produced and their age and condition when marketed. As a consequence, animal life as a natural resource is the basis for an industry which, though of great magnitude, varies in extent from year to year depending on supply and demand. Animal life is an elastic resource responding closely to the demands made upon it. In most countries, the principal domestic animals are counted or estimated periodically and this information serves as a guide for breeding and feeding operations.

**Extent of Live Stock Industry**—As a world resource, cattle exceed all other domestic animals in number and value, aggregating about 6,900,000 head according to current estimates. This term includes all bovine animals, whether kept for beef production, dairy purposes or as draft animals or beasts of burden. In some countries, notably India, buffaloes are included in cattle estimates. Of the world total, Asia possesses about two fifths, Europe about one fifth, with South America, North America, Africa and Oceania following in the order given. Oceania includes Australia and New Zealand. Sheep are the next most numerous domestic animals of economic importance. The world's supply is estimated at about 593,000,000. Of this number, Europe has nearly a third, Asia about a fifth and Oceania slightly less than a fifth. South America, North America and Africa follow.

Swine, though much fewer in number than either cattle or sheep, are noteworthy as a food resource owing to their fecundity and early maturity. The adaptability of pork for curing is also worthy of mention as it permits storage and long shipments without refrigeration. Throughout the world, swine are estimated to number about 255,000,000, of which Asia, Europe and North America respectively have the largest supply. On the other continents, the swine industry is relatively undeveloped. Though the world's animal resources include a great variety of other stock utilized for food, work and sundry purposes, there is a dearth of dependable information regarding their numbers. Even in the case of cattle, sheep and swine, which have just been mentioned as of outstanding prominence, numbers alone give scarcely a true picture of their value to the populations of the various countries. The improved bovine animal as found in North and South America and in the British Isles, where much attention has been given to breeding for beef production, is vastly different from the beast of burden types in India or Mongolia.

Types of sheep vary greatly depending on the relative demand for their wool and meat. Similarly, man's influence on animal life has resulted in swine that excel in bacon production or a high yield of lard depending on the breed selected. Differences in

the use of animal extend to horses, oats, poultry and pet stock. The differences have been brought about through systematic breeding for a long term of years, giving rise to the establishment of recognized breeds embodying the conformation and other qualities. Record associations for the various breeds have served to maintain uniform standards and otherwise to aid in development and improvement. Live stock shows and expositions at which prize are offered for animals of superior merit likewise have been influential in stimulating breeders to their best efforts. In the case of food animals, especially man's skill in the selection of breeding stock has greatly increased the utility value of his herd and flock. Whereas the dressed carcass of an ordinary hog weighs usually between 65 and 75% of its live weight, the proportion is more than 80% in the case of well bred, well managed swine. Moreover, good breeding tends to result in earlier maturity so that animals may be marketed profitably at younger ages with a resulting saving in feed, labour and other expenses. So highly has this feature of stock raising developed that it is not unusual for a litter of pigs from one sow to weigh a ton or more at six months of age. Improved breeding has numerous practical benefits in the raising of other kinds of live stock. Consequently, there is keen competition among progressive stock owners throughout the world in obtaining choice breeding animals.

Inasmuch as the population of the world is increasing steadily, much study has been given to the conservation of animal life in order that it may yield more meat and live stock products per unit of area. In regions where land values have increased, there is need also for economic reasons to reduce losses and to seek greater economy in production. As a consequence, public officials and stockmen have engaged in co-operative endeavours to combat animal diseases and parasites and to stop the ravages of predatory animals. Improved housing and equipment likewise have reduced losses from exposure and the mortality among young animals.

**Veterinary Medicine and Surgery**—Beginning originally in France as a means of saving horses injured in war, there has developed in the more important live stock countries a system of medical service for animals. The science of veterinary medicine and surgery, though designed chiefly to conserve animal life, has made many direct contributions to human welfare. Knowledge of animal anatomy is the basis for the official inspection of meat and meat food products and the veterinary inspection of dairy cows safeguards the milk supplies of progressive municipalities. With veterinary medicine, there has developed also research into problems affecting the health and well being of man and animals alike. The discovery by veterinarians of means to eradicate tick fever from cattle led shortly afterwards to success in combating malaria and yellow fever in man. Knowledge concerning tuberculosis among animals is leading similarly to a reduced incidence of this scourge in the human population, especially among children.

In the light of such information, any statistical measure of the world's animal resources and their usefulness to man in the form of food and clothing must necessarily be incomplete. There can be no accurate appraisal of the service rendered by man's noble friend, the horse, nor by his faithful companion and guarding sentry, the dog. And in the frozen wastes of the globe, the only flesh of animals constitutes the very home fires which maintain human existence. The lower animals are resources which adapt themselves to man's changing needs and if wisely managed give promise of abundance for many generations to come.

(J. R. M.)

## II. VEGETATION

If the great physiographic divisions are exempted, the earth's surface is marked more distinctly by vegetation cover than by any other feature. This fact early attracted man to the study of vegetation as distinguished from the study of the individual plant. Primitive man recognized the plant cover not only as a source of sustenance and protection, but also as a guide in his hunting and planting his food crops. Studies in vegetation and its relation to the factors of the environment began very early.

In the recognition of a plant community (a term used in a general sense to include all groups, large and small), the following criteria may be employed. Physiognomy or the general appearance

the world is divided into three great formation groups covering 1,000,000 sqm of variable grazing land. Of this area 500,000 sqm is suitable for the production of cool weather crops such as wheat and corn while 500,000 sqm are suitable for warm weather crops such as sorghum and cotton and 1,000,000 sqm are suitable for grazing only. The arctic area is divided into two great formation groups covering a world area of 1,000,000 sqm valuable chiefly as grazing land of low carrying capacity and where water is available for irrigation farming. The world contains about 6,000,000 sqm of land suitable for grazing about 1,500,000 sqm of land capable of producing warm weather crops and about 11,500,000 sqm capable of producing cool weather crops. A world no waste land it would limit the production area of the world to less than 25,000,000 square miles.

**Forests—Tropical Rain Forest** is a luxuriant evergreen forest with trees of unequal size and height and of varying age forming a dense canopy of thick leathery leaves and composed chiefly of Leguminosae, Lauraceae, Myrtaceae, Moraceae and Dipterocarpaceae—a true climax forest with trees of all ages and a mixture of many species. Temperature is uniformly high air damp and rainfall 60 to 100 in per year. Soil is greyish or reddish brown poor in humus and containing a large amount of hydrolyzed iron and alumina. Animal life is abundant but chiefly arboreal. Primitive man has lived for the most part at the edge of this forest and civilized man has utilized natural products such as rubber, gum, wood and bark. Cultivated crops are chiefly tropical such as rubber, sugar cane, cacao and tropical fruits, vegetables and fibre plants though temperate ones can be grown. This forest covers 3,800,000 sqm in Africa, South America and the East Indies.

**Temperate Rain Forest** is even more luxuriant and varied than the tropical rain forest. It is a more storied forest rich in mosses, tree ferns and vines. It consists of the southern conifers such as *Podocarpus* and *Waucaria* as well as *Ficus*, *Olea*, *Jumpeus* and *Nothofagus*. The temperature is moderate and the rainfall 40 to 80 inches per year. Under cultivation it will produce temperate cereals and fruits. This forest occupies about 550,000 sqm chiefly in the highlands of Central Africa, South America, south eastern Asia, East Indies and Oceania.

**Deciduous Forest** is characterized by a dense foliage of thin grass green leaves which fall and leave bare branches with heavy bark and scale covered buds during a long cold rest period. Oak, birch, beech, maple and ash dominate this forest. There are two distinct climatic seasons—a warm moist season or growth period and a cold moist season or rest period. Precipitation varies from 30 to 70 in. The soils are either light coloured podzols or grey forest soils. Under natural conditions this forest supports a fauna and fruits and nuts for primitive man. It produced much of the wood and hardwood lumber and has given way to fields of temperate crops and deciduous fruits. There are three great areas of this forest: Eastern United States, western Europe and eastern Asia. The total area is about 6,500,000 square miles.

**Coniferous Forest** presents a uniform stand of similar evergreen trees and consists chiefly of pine, spruce and fir. The winter climate is rigorous rainfall varies from 15 to 100 in. annually the soil is young but the land is of little agricultural value. This forest is the source of much of the lumber used in commerce. It extends across America and Eurasia south of the tundra and

over the mountain ranges north Africa and Mexico. The forest is composed of small trees or a brushland with evergreen clerodendrons ranging from minute ericas to oak like proteas and cherries. Botanically it is extremely variable. The temperature seldom falls below 60°F rainfall is from 0 to 35 in annually and here is a drought period of three to five months. It is an unfavourable habitat for man and animal under natural conditions but under cultivation it is most favourable for the production of citrus and deciduous fruit and cereals alfalfa and vegetables. This forest covers about 1,000,000 sqm chiefly in the Mediterranean region, Cape Province, southern Australia, central Chile and California.

**Grasslands**—In the *High Grass Savanna* the luxuriant grasses range from 5 to 12 ft high and consist chiefly of species of *Andropogon* and *Pennisetum*. The luxuriant growth period is followed by a drought during which the grasses are burned. Annual rainfall ranges from 25 to 75 in. The area varies each year from a grassy swamp to a dry desert. The natural production is not great although the larger animals live here and rubber, oils and ivory are produced. Under cultivation warm weather crops of great variety can be produced. This savanna covers about 800,000 sqm in Africa, south Asia and South America.

The *Tall Grass Savanna* known as Low Veld or Tree Steppe consists of grasses from three to five ft high with trees 10 to 30 ft high scattered through. The grasses are chiefly andropogons and the trees legumes. The temperature is tropical or sub tropical with rainfall of 30 to 80 in. It is excellent grazing land. It is a favourable home for primitive man and for civilized man with rich agricultural lands producing cattle and cool or warm weather cereals and vegetables. It covers a world area of about 3,900,000 sqm in South America, Africa, India and Australia.

**Tall Grass** the prairie of North America, the pampas of South America and the high veld of South Africa are luxuriant pure grasslands of blue stems (*Andropogon*), spear grass (*Stipa*) and wheat grass (*Agropyron*). The climate is temperate rainfall is from 20 to 40 in annually and the soil is unusually deep and rich forming a true *chernozyom* in the dryer portion. There is a short drought rest period followed by a long cold rest period. It is excellent grazing land—it supported great herds of wild game and later cattle and horses which have given way to its utilization as the richest grain fields of the world. It occupies about 1,580,000 sqm in the United States (chiefly east of the 100th meridian), Uruguay and the Argentine, south Russia and Siberia, Rumania and Hungary, South Africa and Australia.

**Short Grass** is only a few inches high occurring in a temperate region with rainfall of 15 to 30 in. with a long drought and a cold rest period. The grama, buffalo grass, spear grass and needle grass are valuable for grazing. The better portion of this land is used for dry farming. The soil is dark brown with an accumulation of

carbonic acid accept of 5 in c... The soil is of high rainfall and is also... in North America South America Africa and Russia.

**Desert Grass** is the most common type of Orchard Thornbush. The soil is of high rainfall and is also... in North America South America Africa and Russia. The soil is of high rainfall and is also... in North America South America Africa and Russia.

**Mountain Grassland** occurs on the high mountains in the tropics. The climate is temperate with 40 to 60 in of rain. The grasses are chiefly species of blue stem (*Andropogon*) (*Eragrostis*) and drop seed grass (*Sporobolus*). It is generally valuable grazing land and under cultivation produces temperate crops as well as bananas and coffee and is similar to the Temperate Rain Forest. The world area is about 90,000 square miles.

**Marsh Grass** occurs in the great swamp areas and consists of coarse grasses. It supports a fauna valuable for meat furs and ivory but without drainage is of no agricultural value. The world area is about 100,000 square miles.

**Desert Shrub and Desert Grass** consists of a sparse cover of low woody or fleshy plants with desert grasses between. Botanical composition varies greatly but legumes, composites, cacti and euphorbias are prominent. Rainfall varies from 5 to 20 in annually. About 10,000,000 sqm of this type are valuable as grazing land of low carrying capacity but valuable for crop production without irrigation.

**Salt Desert Shrub** occupies the low undrained saline basins in all desert regions. It is valuable for grazing land but for agriculture it must be leached of salt. The world area is about 30,000 square miles.

**Desert** in the true sense is seldom found but at least during much of the year many areas seem lifeless. The flora is abundant in species if not in individual and the plants are adapted to the extremes of drought and uncertain moisture supply. The world area in Africa Asia South America and Australia is about 2,400,000 sqm and is of little value.

**Tundra** (including *Alpine Meadow*) shows mixed botanical composition. The growth period is short with a long cold rest period. In summer the temperature rises gradually to 60 or 65 F and during the continuously dark winters the temperature falls to 40 F below zero. This area is valuable for grazing land though not especially productive. The circumpolar world area is about 4,400,000 square miles. (H. L. SH.)

### III. SOIL

In an inventory of the world's resources it is as important to consider the soil in its crop producing capacity as it is to estimate the reserves of coal, copper and oil, substances more commonly thought of in this connection. All of our food, our clothing and many of our utensils, implements and ornaments come either directly or indirectly from the land. (See FOOD SUPPLY OF THE WORLD.)

The crop producing capacity of the soil is however a natural resource in a somewhat different way from that represented by coal or oil. These substances have a definite entity and can be estimated in tons and gallons. Once depleted they are manifestly gone. The soil on the other hand is a resource because of its ability to produce crop-plants. This capacity varies; it may be much reduced and then be definitely rebuilt.

While an accurate and complete tabulation of the soil resources of the world is impossible, the table in the next column gives some idea of the situation. (See SOIL AGRICULTURE.)

Besides indicating the magnitude of the soil resources in acres, the table shows the proportion of the landed area available for crop-plants. This in connection with the population has an important bearing on the possible agricultural and silvicultural independence of each country. Such countries as Argentina, Canada, Australia and Russia can support much larger populations. Their forest resources in terms of population are also great.

TABLE 1  
Estimated Areas of Ploughed and Forest Lands  
in the Principal Countries of the World

Country	Ploughed lands			Forest lands		
	Acres in millions	% of land area	Acres per person	Acres in millions	% of land area	Acres per person
Argentina	264.00	55.8	25.5			
Canada	90.20	4.7	14.6			
Denmark	596.75	25.3	6.7			
France	25.51	18.8	6.6			
Germany	30.90	6.5	5.5			
British India	86.51	1.9	3.3			
Italy	13.96	18.2	3.3			
Japan (mainland)	48.44	51.4	8.1			
Sweden	55.50	54.8	9.1			
Great Britain	2.74	4.8	0.6			
United States	550.00	8.3	4.5			
South America (U.S.)	1,071.8	3.1	1.1	1,984.55	42.8	0.9

1. Includes agricultural area estimated at 250 million acres.

2. Cropped area will ultimately be much greater.

3. Includes agricultural area estimated at 300 million acres.

4. Includes agricultural area estimated at 700 million acres.

With our rapidly increasing world population two major soil problems present themselves: *first* the possibility of increasing the area of lands growing crops other than forests and *second* methods of preventing soil depletion and consequent crop decrease. The utilization of virgin and well watered grass lands and the reduction of our forest areas have met the first problem in times past. Unfortunately soils have often been deforested and put under cultivation when they should have been left with their forest cover.

The reclamation of swamps and the better drainage of crop bearing lands have increased the area and effectiveness of the cultivated soils. (See DRAINAGE RECLAMATION OF LAND.)

The utilization of arid and semi arid lands is particularly promising in certain countries. Such soils developed under low rainfall are potentially fertile. Thousands of acres of arable and very highly productive lands will ultimately be added to that now available for crop production through irrigation (q.v.).

Another important means of utilizing semi arid soils is by dry land farming. (See AGRICULTURE.) By proper methods of cultivation moisture is conserved in the soil and carried from one season to the next. Farming operations thus become possible in areas where the annual rainfall is as low as 20 inches.

The second major soil problem relates to the maintenance of soil fertility. Land can not be cropped without certain losses taking place. These losses are four in number: *first* erosion or the removal of the surface soil, the most fertile portion, by water or wind; *second* the loss of constituents by the drainage of water through the soil called leaching; *third*, the removal of nutrients by plants; and *fourth* the loss of organic matter as a result of biochemical oxidation and the liberation of carbon dioxide.

Water erosion may be controlled by small dams, by terraces and by the use of sod crops. In spite of such possibilities however thousands of tons of fertile soil are swept annually into our rivers. In many cases this is the major cause of soil depletion and is closely correlated with deforestation and flood devastations.

The losses through drainage, crop removal and organic oxidation are susceptible of but little control. Farming operations even the most careful encourage rather than check such depletions.

The major features of soil fertility maintenance may be very simply set forth if it is taken for granted that the soil drainage is good, that tillage is adequate, that erosion is under control and that a suitable crop rotation if possible is utilized. Under such conditions the problem is to add certain constituents in such amounts and proportions as at least partially to offset the inevitable losses. At the same time the physiological balance of the plant nutrients should be maintained as nearly as possible.

While plants require ten nutrient elements for their normal growth and probably several more besides, ordinarily only four are likely to become especially critical, namely nitrogen, potassium, calcium and phosphorus. Sulphur also may be a limiting

It is then in the arid and semi-arid regions of the world that the production of a reliable crop is most difficult. The knowledge of the value of irrigation was developed by the ancient Egyptians. No other civilization had the knowledge of irrigation and the development of irrigation in the Near East and Mesopotamia. With the decay of the Egyptian empire the knowledge of irrigation was lost. The Mesopotamia exposed to the full force of the successive surges of Mongolian nomads received blows from which it has never recovered. With the advent of the Renaissance and the gradual growth of modern civilization the centre of civilization gradually shifted to the more humid part of northern Europe and eastern North America and artificial moisture became a less important factor in the growing of the world food supply.

After 1850 new influences in world affairs gave a decided impetus to irrigation development. Railroad construction has opened up vast areas of arid and semi-arid lands requiring irrigation to bring them to a high degree of crop production. Construction equipment and method have been greatly improved. Projects are now feasible which a half century ago would have been entirely impracticable. Dams are projected and under construction of a height and size undreamed of a few decades ago. Improved standards of living have increased the demand for certain products of irrigated lands such as citrus and deciduous fruits and increased transportation facilities have made possible their wide spread distribution. As a result the irrigated areas in the newly developed countries of the Western Hemisphere have been increasing rapidly. The population of India, China and other lands of ancient civilization has been very largely limited by the area of tillable land and this in turn by the supply of water available for irrigation. The very considerable growth during recent years in the population of India has been due in large measure to the effectiveness of the irrigation works constructed by the Government. Probably one fourth of the population of the globe is now primarily dependent for food on the products of irrigated land.

The irrigated area of the world by countries in 1916 has been estimated by the U. S. Bureau of Reclamation as practically 100,000,000 ac. made up by continents as follows: North America 68,400,000 ac. South America 6,613,000 ac. Europe 14,198,000 ac. Asia 140,760,000 ac. Africa 10,510,000 ac. Oceania 1,270,000 ac. grand total 200,583,000 acres. (F. F. H.)

#### V FISHERIES

The important fisheries of the world are found for the most part within the north temperate zone chiefly between the 40th and 60th parallels of north latitude. In this region conditions are especially favourable to fish life including large continental shelves with relatively shallow water and extensive coastal indentations richly supplied with materials from the massed land areas of the region to support an abundant aquatic flora and fauna. The herrings of which there are some 150 species represent the most important family of fishes. The species are widely distributed in fresh and salt water and contribute a greater yield than any other family of fishes. They supply the raw materials for the highly important sardine industries of Norway, France, Spain, Portugal and the United States, the extensive herring curing industries of northern Europe and North America, extensive fish meal fertilizer and oil industries of Norway, United States, Canada and Japan, as well as being widely used for food in the fresh state wherever they are found. As they feed on microscopic plant and animal forms they are especially important as converters of plankton organisms at one step into food for man.

The gadoid fishes which include the cod, haddock, hake and pollock also rank high in their contribution to man's needs. The annual catch of cod along the Atlantic coast of North America exceeds 1,000,000,000 pounds. These are white meated fishes and the fat is stored in the livers the basis for the cod liver oil industry. Next in importance are the salmon, noted for their exceptional food properties, size, beauty and gameness. The family includes not only the salmon but the white fishes, the ciscoes or

lake herring and the trout. The most important members are the five species of salmon native to the North Pacific entering the tributary river in North America and Asia to spawn. The annual catch amounts to about 1,000,000,000 lb. a year and is the basis for the important salmon canning and curing industry.

The mackerels of which there are about 60 species are widely distributed and highly prized for food in the areas where they are found in abundance. Included in this family are the highly prized tuna, the true mackerels of the north Atlantic, Spanish mackerel and the bonito. The shell fish fisheries are also of considerable importance including some of the choicest products of the sea and valued as food because of their distinctive flavour and their richness in iodine and minerals, essential elements of our diet. The oyster fisheries are of importance in the United States, France and Japan. Lobsters, crabs, clams and shrimp are widely sought after.

The fisheries are a most important source of food. In addition they supply many articles of importance in the arts and industries. Fish meal is gradually winning a place for itself as one of the most valuable protein feeds for hogs, cattle and poultry. Fish fertilizer is generally recognized and widely used as a plant food. The demand for and use of fish oils for soap making for hydro generation including use in lard substitutes and for many other purposes is increasing. About 60,000,000 gal. of whale oil alone is now produced annually. Shells of molluscs are an important source of raw materials of buttons and various artistic articles. From the shells of the fresh water mussels taken in the Mississippi valley region are produced about 3,000,000,000 buttons per year. From shark hides are made fancy leathers for artistic articles. From fish scales is derived fish scale essence used in the manufacture of imitation pearls from Japanese pearl farms are derived artificial pearls and from numerous waters of the globe are taken genuine pearls. From the sea weed industries are derived many products and from the sea itself the indispensable solar salt.

The annual world harvest of fish and fishery products amounts to not less than 50,000,000,000 lb. with a first value of about \$1,500,000,000. In addition there is a very considerable draft on water areas by angler and fisherman for home consumption for which no satisfactory estimate can be made. Among the leading nations of the world in the prosecution of fisheries arranged in the relative order of the magnitude of their fisheries are: Japan with a catch of about 5,700,000,000 lb., United States with 3,000,000,000 lb., England 1,700,000,000 lb., Norway 1,450,000,000 lb., Russia 1,200,000,000 lb., Canada 1,190,000,000 lb. and Spain 900,000,000 pounds. These seven countries produce about one half of the world's fishery harvest. Among the other nations producing in excess of 500,000,000 lb. annually are Scotland, Newfoundland, Germany, France and Portugal. (L. R. A.)

#### VI FORESTS

The world production and consumption of wood amounts to approximately 56,000,000,000 cu. ft. which is an average of 3 cu. ft. per caput. About 26,000,000,000 ft. is saw timber and 30,000,000,000 ft. is firewood.

**Increase of Consumption**—As populations grow and as living standards rise and human wants become more complex, timber consumption increases in spite of the extensive and growing use of substitute materials and in spite of the tendency to utilize wood more economically. Railroad ties, newsprint and other products of wood pulp, automobiles, phonographs, radio cabinets and many other articles requiring large quantities of wood all have come into extensive use within recent times.

In Great Britain timber consumption has increased much more rapidly than has the population. Even in France with a practically stationary population timber consumption was slowly increasing until 1914, that of Germany more than doubled within the century. In the United States at least seven times as much lumber is (1929) used as in 1850. Judging from the rates of increase in these and other important consuming countries the world's timber needs may be expected to double within approximately 50 years. The per caput consumption in North America of saw timber (188 cu. ft.) is five times as great as that of Europe and if the tropical countries south of the United States be disregarded it is six and one half times that of Europe. Europe

South America and Australia use about 1 cu ft of wood per capita (39 cu ft). The proportion of wood used here is the ninth in South America two in the United States and in Europe Asia and Africa use comparatively little wood (9 and 5 cu ft respectively).

The total quantity of wood grown in the world is roughly estimated at 100,000,000,000 cu ft. The annual increment were spread evenly over the whole of the world would amount to only 51 cu ft per acre. In the United States the present annual growth of 80,000,000 cu ft is not replacing the present annual cut of 56,000,000 cu ft. The annual growth each year represents the growth of only a small part of the forest. Vast areas of virgin forests are being lost to the world because in their present condition there is no use for them. If all the forests of the world were placed in a growing condition with a moderate amount of management and protection against devastation they could produce annually at least 555,000,000,000 cu ft of wood or nearly 100 cu ft per acre.

**The World's Timber Supply.**—With about 100,000,000 ac of productive forest area in the world bearing heavy stands of virgin timber having possible growth rates of 10 to 20 ft per year the world's present timber requirements it would seem that there is enough timber to last for centuries. This would be true if all kinds of wood were equally capable of satisfying human wants. There are about 645,000,000 ac of softwoods or conifer forests in the world, some 1,040,000,000 ac of temperate hardwoods or broad leaf forests and 638,000,000 ac of tropical hardwoods. Although the softwood and temperate hardwood forest together form only one half of the total forest area of the world 91% of all the timber cut and used comes from the softwood and temperate hardwood forests of the Northern Hemisphere and only 9% from the tropical hardwoods. The softwood forests are furnishing three fourths and the temperate hardwoods one fifth of the construction timber of the world. The temperate hardwoods in addition supply three fourths of all the firewood. The amount of standing timber in the tropics is far greater than the amount remaining in the temperate regions, yet until recently the tropical forests have played a minor part in supplying the world's timber. There has been prevalent an idea that the tropical forests are composed chiefly of cabinet woods, dyewoods and similar kinds of hard heavy deeply coloured wood suitable for furniture and special uses but not for construction. Recent explorations have shown that there are many excellent construction woods equal if not superior to the woods of conifers for use in the tropics because more resistant to decay and termites. Before the tropical forests are able to supply a large part of the world's requirements there must be developed adequate systems of cheap transportation and adequate supplies of efficient labour. Another difficulty is that the tropical forests are mostly composed of a variety of species intermingled in the greatest confusion and can be exploited economically only if practically all the important species can be utilized. The crux of the world's timber supply problem during the next two or three generations at least lies in the available supplies of softwood and temperate hardwood.

**Softwood Supplies.**—The softwood forests are very largely confined to the cooler regions of the Northern Hemisphere although some conifers occur in the Southern Hemisphere. The present growth of conifer timber is about 80% of the present cut. The forest capital is being depleted. The principal conifer regions are (1) North America including Canada, the United States and the Sierras of Mexico, (2) northern Europe and central Europe, (3) Asiatic Russia, Manchuria and part of Japan.

In *Canada* the total amount of accessible merchantable saw timber is estimated at approximately 61,500,000,000 cu ft and of pulpwood 52,000,000,000 cubic feet. The forests are being destroyed from two to two and one half times faster than they are grown. At a total annual drain upon the forests of 5,000,000,000 cu ft the accessible stands of virgin forests would be exhausted in about 5 years. In the *United States* roughly only 385,000,000,000 cu ft of softwoods of saw timber size remain. Softwoods comprise two thirds of the 13,000,000,000 cu ft of

timber in the United States. The present annual growth of softwood timber in the United States is about 10,000,000,000 cu ft. The present annual cut is about 12,000,000,000 cu ft. The present annual growth of softwood timber in the United States is about 10,000,000,000 cu ft. The present annual cut is about 12,000,000,000 cu ft.

In *Asia* the only country exporting on a large scale at present is Japan. In *Asia* only western and eastern Siberia are reputed to have enormous supplies of virgin softwood timber. Siberian forests however are largely unexplored and little is known of their actual condition. Of the forest area of *South America* only 5% is composed of conifer. The bulk is in southern Brazil and adjacent portions of Argentina and Uruguay. The entire region produces only from one third to one half as much softwood timber as Argentina alone buys from the United States and Canada. The other South American countries depend upon the Northern Hemisphere for much of their construction timber.

*Africa* although it possesses extensive equatorial forests does not contain enough softwood timber to furnish even the small amounts required locally for construction purposes. In *Australia* the softwood supply is inadequate for local needs. Much pine and spruce lumber is imported from North America, Europe and northern Asia. The small area of softwood forest in New Guinea and the other islands of the Pacific is insignificant.

Lord Lovat after a survey of the softwood forests of the world arrives at the conclusion that except in Russia the main softwood virgin timber reserves will be exhausted before very long and Europe will have to depend more and more on timber raised by the agency of man. That the United States shortage is likely to come more quickly than that in Europe, that the more the American supply becomes centred in the Pacific coast States the greater is the probability of the industrial States of north eastern America coming into the European markets for saw timber in the same way that they do now for pulpwood and finally that as the United States consumes over 13,000,000,000 cu ft of softwoods as opposed to a total European consumption of 9,000,000,000 cu ft the United States advent into European markets will have an important bearing upon European prices.

**Temperate Hardwoods Supplies.**—Like the conifers the temperate hardwoods are confined chiefly to the Northern Hemisphere and are located fairly close to consuming centres. They as a rule occupy the better soils of the more favourably situated lands and therefore have been progressively destroyed to make room for cultivation. The large old timber has been depleted even to a greater extent than that of the softwoods. *Europe* has still extensive areas of hardwood forests and even exports special kinds such as the oak of Poland and Yugoslavia. On the whole however the consumption of hardwoods in Europe greatly exceeds the production. In *Asia* Japan exports small quantities of oak, Walnut and other hardwoods are exported from Asiatic Turkey and the Caspian region. *Siberia* has about 30% by area of the temperate broad leaved forests of the world. Except in the Far East however they consist of fairly light stands of aspen and birch much of it valuable chiefly for firewood or pulp and not to be compared with the hardwoods of the United States and Europe. In *North America* the United States now has the largest supply of temperate hardwoods. The other North American regions have no surplus over their own needs. The original stand of approximately 250,000,000,000 cu ft of merchantable hardwoods has dwindled to about one-fourth of that amount and is being further depleted at the rate of over 2,000,000,000 cu ft

a year. The United States has 400,000,000 cu ft of hardwood timber a year. The rest of the world has almost two thirds of the entire world consumption of temperate hardwood timber. In the entire production of the Southern Hemisphere including *Chile* and *Argentina* of *South America* and *Africa* there are relatively small quantities of valuable hardwood timber available for export. The outlook for future supplies of hardwoods however is probably better than for oil. Wood-based products added to the measures can be got from the tropical forest though they are not so much more. (R. Z.)

#### VII NATURAL GAS

The occurrence of natural gas is widespread both geographically and geologically. Geographically natural gas is produced in (1) United States: Alaska, Arkansas, California, Colorado, Illinois, Indiana, Kansas, Kentucky, Louisiana, Michigan, Missouri, Montana, New Mexico, New York, Ohio, Oklahoma, Pennsylvania, South Dakota, Tennessee, Texas, Utah, West Virginia, and Wyoming; and (2) Canada: Alberta, New Brunswick, Ontario, and Saskatchewan. It is found beneath the earth's surface compressed in small cavities or in porous rock strata. The gas sand is a porous rock formation containing millions of small cavities which gas, oil, water or all three together may occupy.

There is a considerable difference of opinion among geologists and chemists as to the origin of natural gas. There are two theories—the organic and the inorganic. In the former natural gas is considered as having been formed as the result of a tremendous distillation process of decayed vegetable and animal matter millions of years ago. The inorganic theory places the origin of natural gas at a still greater age back into the beginnings of the world and regards it as a product of heat and volcanic action on carbon possibly deposited when the first crust of the earth was formed. The organic theory is the one more generally accepted. It is a well established belief however that regardless of the process by which natural gas came into existence the new gas now being generated underground is negligible so that when the present supplies are exhausted natural gas will fail.

The by-products of natural gas are natural gasoline, helium, chloroform, formaldehyde, formic and other acids. An important use of natural gas is in the manufacture of carbon black produced for the manufacture of printer's ink and automobile tyres.

More than 1,000,000,000 gal of gasoline were (1929) being recovered as a by-product thus adding to the total supply of motor fuel. Also many millions of cubic feet of liquefied petroleum gases were produced and marketed as raw materials. Many thousand pounds of medicinal, synthetic and pharmaceutical preparations were made. It has been estimated that 100,000,000 cu ft of helium could be produced annually.

The natural gas industry is of most importance in the United States where its magnitude is indicated by the fact that between 15 and 16 million persons living in some 2,500 cities and towns in 24 States represent the domestic consumers of natural gas. In addition possibly 17,000 industrial concerns utilize this fuel. The supply of gas is drawn from more than 45,000 wells covering an area of over 15,000,000 acres. The expansion of natural gas service by means of long high pressure transmission lines to distant towns is one of the outstanding features of the public utility situation in many parts of the United States, natural gas replacing manufactured gas at many important centres.

As in the petroleum industry pessimistic opinions prevalent a few years ago regarding dwindling supplies of natural gas have been forgotten as a result of the enormous developments of 1929.

Drilling for gas, even with the modern and improved methods is generally quite uncertain. Expensive drilling is the only means of definitely determining whether gas exists in paying quantities. Thus out of a total area of 3,000,000 sq m in the United States, less than 12,000 sq m have been productive of natural gas. Geologists are able to indicate probable productive or non-productive lands with a reasonable degree of accuracy, but not with sufficient accuracy to establish a safe estimate of the probable reserve.

In recent years much attention has been given to the conservation of this fuel. Since natural gas is so often incidental

to the recovery of oil it is in many cases largely wasted—acting merely as the vehicle which propels the oil out of the oil sand. (F. W. PA.)

#### VIII COAL

Since the estimate of the coal resources of the world was made in 1913 by the International Geological Congress the World War and the Versailles treaty have changed many boundaries and consequently the resources of many nations. The best revision of these figures for Europe is that by Sir Richard Redmayne and it is used for European figures in the accompanying table. It does not show the quantities of various kinds of coal in European countries a task that must be left to some future congress. Neither Sir Richard Redmayne nor the International Geological Survey gives consideration to the exhausted minerals except that the United States figures are corrected to 1910. Because of the impossibility of correcting all the figures owing to the changes in boundaries and to inadequate data as to kinds of coal extracted and even as to total extraction in some countries no attempt has been made as it should have been to correct for consumption and waste in mining. The figures for Ireland have been energetically debated. Those given by the congress may be too low especially in view of some recent discoveries. Nevertheless, the figures of the congress have been taken without change including those of England though there also extensions of fields have been indicated without definite estimates of their importance. Some changes were made in the figures for Panama, Pennsylvania, Rhodesia, Victoria and British Columbia the last because the report of J. D. MacKenzie has shown the resources of Vancouver Island to be probably overestimated.

Using the figures in the table on p. 865 and the figures for production of coal in the 1925 publication of the Bureau of Mines (Department of Commerce, United States) *Mineral Resources of the United States* it is found that the 1925 production of coal in the United States was about 58 million tons while the coal reserve in the United States is estimated at 4,231,076 million tons. This shows a supply of over 7,000 years on the basis of the 1925 production. Similarly for the world with a coal reserve estimated at 7,861,600 million tons and a 1925 production of about 1,498 million tons a supply of over 5,000 years is shown based on the 1925 production. These figures indicate that even with large increases in coal consumption it will take many years to exhaust the known world resources as estimated in 1925.

In the table A represents anthracite, B is coal with volatile matter between 12 and 35%, C is coal lying between B and a coal D the moisture in which exceeds 20%. (R. D. H.)

#### IX PETROLEUM

In discussing the petroleum resources of the world the best that can be offered is a scientific guess carefully formulated on the basis of the data now available. Probably the best available study is that by Eugene Stebinger, chief of the Foreign Mineral Section in the U.S. Geological Survey (made in 1919) on a map upon which he indicated by circles the relative importance of the estimated oil reserves of the different regions. Stebinger's estimates follow the table on p. 866 expressing first the relative values of these groups as compared with unit value for the United States and second the corresponding quantities when unit value for the United States is 7,000,000,000 barrels.

Since the Stebinger estimates there have been several careful investigations and reports on the oil reserves of the United States. Petroleum recovered by present methods of flowing and pumping from existing wells and acreage thus proven in the United States amounts to 5,300,000,000 bbl. according to an estimate made by the Committee of Eleven of the American Petroleum Institute in 1925. The report estimates that after pumping and flowing there will remain in the area now producing and proved 26,000,000,000 barrels of crude oil, a considerable portion of which can be recovered by improved and known processes such as flooding with water, the introduction of air and gas pressure and mining, when price justifies. Improved methods of deep drilling below oil sands now producing will disclose in many areas deposits not hitherto available, which will be tantamount to the discovery of new fields.

The Federal Oil Conservation Board has estimated that the reserves of oil in the United States are about 450,000,000 barrels. The Board has also estimated that the reserves of oil in the world are about 1,000,000,000 barrels. The Board has also estimated that the reserves of oil in the United States are about 450,000,000 barrels. The Board has also estimated that the reserves of oil in the world are about 1,000,000,000 barrels. The Board has also estimated that the reserves of oil in the United States are about 450,000,000 barrels. The Board has also estimated that the reserves of oil in the world are about 1,000,000,000 barrels.

known in regions not indicated on the Stebinger map although in most such instances the geological conditions seem to preclude reserves of great importance and that there are in other countries many untested regions in which the geological conditions appear to be favourable for the occurrence of oil fields though surface indications of oil have not yet been reported possibly due in part to insufficient exploration. It is highly probable he said that oil in considerable amounts will eventually be discovered in areas of north west Canada. Other regions outside of the United States in North America which seem likely to make contributions possibly of minor importance include Central America, Santo Domingo and lower California. In South America important new centres of production seem probable along a very extensive strip of territory bordering the east surface of the Andes and in addition areas of north eastern Brazil are possibly oil bearing.

Madagascar offers much promise and conditions favourable for developing oil fields appear to be present not only in Angola and other regions of west Africa but possibly in east Africa also. Australia, Tasmania and New Zealand may yet disclose producing areas of value and it seems reasonable to expect new discoveries of importance in parts of India not on the Stebinger map. Arabia, Palestine, Armenia and Anatolia all offer thoroughly circumstantial indications.

Also it seems rather probable that oil will be produced in portions of Spain, Austria and other countries of western Europe. Considerable extension of the known Russian oil areas may be expected and Siberia, about which geological information is so greatly desired and which is said to carry indications of oil deposits in Transcaspia, Turkistan, Kamchatka and notably in northern Saghalien, may reasonably be expected to contain oil bearing areas. China has oil indications in at least four of her provinces. It appears probable that oil is present scattered from Persia and Transcaspia eastward as far at least as Gobi. There are possibilities of oil in the Philippine Islands.

Evidence as to the probable presence of additional oil reserves in the areas just reviewed leads White to conclude that there are probably 20,000,000,000 barrels of oil available in the world—in addition to the 43,000,000,000 barrels contained in the regions covered by Stebinger's estimates quoted above or as much in round numbers as 60,000,000,000 barrels in all.

**Petroleum Substitutes**—The chief substitutes for petroleum now available is oil obtained by distillation from oil shale and from coal. Though oil shale is now utilized in only a few countries it is widely distributed throughout the world and the oil shale resources of the United States are so extensive as to furnish a guarantee for the future. In North America oil shale occurs in both Canada and the United States but is commercially undeveloped.

Large areas in the eastern United States and eastern Canada are underlain by dark shales of the Primary or Palaeozoic age that are in many places as rich in organic matter from which oil can be distilled as those mined commercially in Scotland and France.

Comparatively little is known about oil shale in South America although it is said to occur in Argentina at several localities in Brazil and Chile. Unprofitable attempts have been made to drill oil from oil shale in eastern Brazil. In Africa thin beds of bituminous shale capable of yielding oil when distilled are reported from Angola, the Belgian Congo, Natal and the Transvaal. Perhaps the largest area of oil shale is in the Belgian Congo.

In Europe the commercial development of the oil shale industry began early in the 19th century before the rise of the modern petroleum industry. About 91% of the world's oil shale output is produced in Scotland and 8% in the Autan and Aumance districts in Lorraine and France and the remainder in Australia, Germany and Italy. In Scotland the oil shale industry has been able to compete successfully with the petroleum industry because of the output of valuable by-products made in connection with the oil and because of the remoteness of Scotland from the principal sources of petroleum—southern Russia and the United States. Large deposits of oil shale are reported to occur in northern Russia. Oil shale in Asia is not mentioned in any report that has been seen but valuable deposits may nevertheless exist there.

Formerly oil shale was mined and distilled in Oceania at several places in Australia (most of them in New South Wales) and in New Zealand. But the total shale oil produced in all these places has amounted to less than 1% of the world's output.

The U.S. Federal Conservation Board estimates a supply which can be recovered from domestic oil shale if and when the price warrants its extraction of 9,000,000,000 bbl. nearly ten times the total quantity of oil that has been produced in the United States from 1859 to 1929. At the present rate of production from well this quantity would suffice for roundly 100 years. The estimate is made that the two and one half trillion tons of bituminous sub-bituminous and semi-bituminous coal in the United States within 3,000 ft. of the surface is capable of yielding about 92,000,000,000 bbl. of motor fuel more than 300 times the motor fuel production in 1927. It is also estimated that another 12,000,000,000 bbl. of motor fuel may be obtained from the 940,000,000 tons of lignite deposits in this country. This would make available an estimated total quantity of 104,000,000,000 bbl. or 4,264,000,000,000 gal. of fuel for motors in addition to the numerous billion barrels of crude oil from wells and oil shales. (L. M. F.)

### METALLIC AND NON-METALLIC GROUPS

Under this heading are discussed the most important metallic and non-metallic substances including Iron, Lead and Zinc, Copper, Aluminium, Nickel, Manganese, Tin, Tungsten, Vanadium, Sulphur, Mercury, Silicon and Mica.

#### I. IRON

Broad allowances for incomplete information must be made when considering iron ore resources. While no new immense iron ore fields remain to be discovered in either Europe or North America the remaining four continents are still largely unsurveyed. Of known iron ore reserves 15,000,000,000 tons occur in North America, 12,000,000,000 in Europe and 7,000,000,000 in South America. If it be assumed that the remaining three continents are proportionately as well supplied—and against this assumption there is no geological argument—the conclusion is reached that the world iron ore reserve is a total of 90,000,000,000 tons.

The world was in 1919 using annually some 150 million tons of iron ore. This was supplied by many mines but a few great ore fields were responsible for the bulk of the tonnage. The Lake Superior iron ore region in the United States ships some 60 million tons annually and the Lorraine field of France and Luxembourg about 40 millions. The fields of Great Britain rank third with around 13 million tons and the Alabama region of the United States fourth with some 6 millions. After that ranging from 5 million down to 1 million annually come Spain, Sweden, Manchuria, western France, Newfoundland, Cuba and North Africa.

The localization of demand may cause more concern than excessive total consumption for a few ore fields are being drawn upon in exceptional tonnages while other large fields are practically unused. For example, if the present day drafts continue

our current estimates of known ore reserves in the field suggest that ore of present value will last in the Lake Superior region within 100 years, in Britain within the century and in the United States against the far off threat of exhaustion. The present drafts the Albarado fields in Brazil while the vast reserve of Bauxite in the United States can remain in production for many years. That soon the old iron ore of the United States can lead ship will in the heavy iron ore market challenged by a new European competitor from the Norman ore fields and upon west European fields.

With regard to the four continents which are less known and less developed industrially existing knowledge of ore and fuel supplies permits certain deduction of certain validity. It may be safely assumed for example that the coal supplies of Asia particularly in China and India will increase and encourage a large iron and steel industry as local consumption increases and that under certain conditions the excess production may be exported so as to become a serious factor in European and North American trade and industry. With regard to South America Africa and Australia present knowledge of raw material resources suggests that while Australia may easily become self supporting in the way of steel and iron products the other two are likely to become important as exporters of iron ore to coal rich areas but not as serious producers of iron and its products. Older conclusions as to iron ore exhaustion have been modified seriously by the fact that within the past two decades their bases of deduction have been strikingly changed. For 150 years the world iron industry had increased at the rate of 50% each decade and most earlier estimates prolonged this past rate of increase into the indefinite future. Now for the first time in the history of modern industrialism there has been experienced a period of 15 years in which the world iron industry has not progressed and there is no reason to assume that whenever this dead point is finally passed over the old rate of increase will be resumed. It is indeed far more likely that in the future the iron industry of the world will increase at a far slower rate possibly not above that of the rate of increase of world population. If so the known ore reserves will last for very many generations. (E. C. E.)

## II LEAD AND ZINC

**Lead**—No quantitative estimate of the copper lead and zinc resources of the world has been made and it is doubtful whether a reasonable approximation can be made. Looking backward through 50 years there have been periods when it was thought that the supply of these ores was superabundant and other periods when they have seemed to be scarce and opinion has swung from one extreme to another. Especially has this been true in the instance of zinc. However as to each of these metals new discoveries both geographical and technological may develop valuable resources out of what was previously unknown or worthless. The only conditions under which the world's resources of minerals can be reasonably forecast are when we may say that at least we have so much as in the instances of coal and iron. Between these extremes it is always a matter of the equilibrium among production consumption and price. So far as we can see ahead we shall have a sufficient supply of these metals but we can not see clearly what price we shall have to pay for them even through the next 10 years.

The production of lead comes principally from the following districts their percentages being given: South eastern Missouri 11.7, Utah 8.6, Coeur d'Alene (Idaho) 7.5, Tri State covering the contiguous parts of Oklahoma, Kansas and Missouri 5.9, Mexico 12.6, Spain 9.2, Broken Hill N.S.W. 9.5, Sullivan mine Kimberley B.C. 7.5, Bawdwin mine Burma 3.5. These places account for about 76% of the world's production. Except in south eastern Missouri the mines produce a mixed ore which is milled so as to give an enriched galena product for the lead smelter and a blende product for the zinc smelter. Many of the

have past been exhausted or lead ore is being exhausted. The world's production of lead is about 1,000,000 tons annually. The United States produces about 100,000 tons annually. The world's reserves of lead are estimated to be about 100,000,000 tons. The United States has about 10,000,000 tons. The world's production of zinc is about 1,000,000 tons annually. The United States produces about 100,000 tons annually. The world's reserves of zinc are estimated to be about 100,000,000 tons. The United States has about 10,000,000 tons.

**Zinc**—The world's production of zinc is about 1,000,000 tons annually. The United States produces about 100,000 tons annually. The world's reserves of zinc are estimated to be about 100,000,000 tons. The United States has about 10,000,000 tons. The world's production of lead is about 1,000,000 tons annually. The United States produces about 100,000 tons annually. The world's reserves of lead are estimated to be about 100,000,000 tons. The United States has about 10,000,000 tons. The world's production of zinc is about 1,000,000 tons annually. The United States produces about 100,000 tons annually. The world's reserves of zinc are estimated to be about 100,000,000 tons. The United States has about 10,000,000 tons.

On the other hand new sources of production are being developed as the results of exploration of new territory the extension of transportation and improvement of metallurgical processes which not only make it possible to use profitably ores that formerly were considered refractory but also to give an increased yield from all ores. Among the new districts that are making or are promising a yield are: Elm Flon, Sudbury, Buchan (N.F.), Broken Hill (N.S.W.), Roschery (Ta.), Mount Isa, Cerro de Pasco (Peru). By 1910 most of these will be producing. A general upward trend of price was expected in 1913 as a consequence of the increasing scarcity of zinc ore but the advent of selective flotation changed that outlook almost immediately. Portions of the world as yet unexplored scientifically may have great zinc ore possibilities as northern Canada wherein important deposits are now being opened, Labrador, Newfoundland, the Andes, Siberia where there are some great known deposits, Africa especially in the north and in the Congo region and in Rhodesia, the interior of Australia and in New Guinea.

The production of ores up to the present time has been from deposits whereof there have been surface indications. Much of the world's surface is covered by alluvial material which probably hides mineral deposits. We are on the eve of advances in geophysical science and methods that are opening the way to the discovery of such hidden deposits. On the side of requirements the need for all of these metals steadily increases. Immediately previous to the World War the annual per caput consumption of the United States was about 5 lb. of copper, 9 of lead and 6.5 of zinc. In the principal countries of Europe the average was a little less especially of copper. In 1913 the American per caput consumption was about 15 lb. of copper, 12 of lead and 10 of zinc. European consumption was however, still below the pre war rate. A continuing increase may be expected in America and in Europe a regaining of pre war rate and then advances. These prospects as to requirements follow from the intimate association of copper and lead with electrification and with storage batteries. For lead there is no general substitute although aluminium is employed occasionally for electrical transmission. Though hardly to be rated with copper and lead, zinc is used to an important extent in brass and in paints it replaces lead when the latter becomes scarce. (X.)

## III. COPPER

The recent history of the copper industry is closely related to the tremendous development of the electric industry in the last 20 years. In 1913 the output of the total world output of the metal was controlled by three industries. World production for the ten year ending Dec 31 1900 was 1,135,515 tons for the ten year ending Dec 31 1910 approximately 1,115,500 tons. In the earlier period the United States furnished 53% and in the later 55.9%. South America's proportion rose from 34% to 16% and Africa's from about 1% to about 5%. The total recorded output of the world since 1800 has been about 91,700,000 tons one half of which has been supplied by the mines of the United States. Indications are that South America Africa and Canada will increase their proportion in the next ten years. Prior to the exploitation of the large bodies of the porphyry or low grade copper ore it was not customary for the copper producing companies to publish statements of reserves of ore in the ground. The porphyry companies report reserves because in general the exploration of such a deposit can be done very cheaply by drilling many years in advance of mining operations.

The so called 'dear level' or vein mines still adhere to the practice of not publishing reserves because of the large amounts of money required to explore such deposit much in advance of actual mining and the probability that if such a policy were pursued the work would largely have to be done over again when mining operations overtook exploration. The general practice of these companies is to keep exploration four or five years ahead of mining gauging against past performances the amount to be done by the relative rate of discovery per foot of development. Published estimates of reserves in porphyry mines have included only such material as could be treated profitably at the time of the estimate. Lower cost per ton of ore increased recovery of metal per ton of ore and higher price of metal all tend to lower the minimum grade of ore that can be treated profitably.

Several important companies are now making money by the extraction of ores which do not contain over 15 lb of the metal to the ton while 25 years ago the minimum grade which could be profitably handled was more than double this amount. The Rio Tinto district in Spain has been producing copper since the days of Caesar and in 1914 had an output in the neighbourhood of 70,000,000 pounds. The last official statement of ore reserves by the principal company in this district was made in 1905 at which time the reserves were estimated at 60 years supply. Since then highly important discoveries have been made.

The Mansfeld Copper Company mines in Germany have been exploited for several centuries and are now producing between 30,000,000 and 40,000,000 lb annually. The first recorded production from this district was about A.D. 1200. Attention has been recently attracted to developments in Chile and Peru. One hundred years ago Chile was one of the chief copper producers of the world and the copper deposits of Peru with associated high grade silver ores were known to Pizarro. With cheaper sources of supply in the United States importance waned in these deposits only to be revived in the present century with the recognition of the availability of large deposits of copper ore containing 40 to 50 lb per ton which could be profitably exploited on a large scale.

The latest official estimate of the reserves of the Chile Copper Company shows about 700,000,000 tons of 2.12% copper from which about 24,000,000,000 lb of the metal are recoverable by present known methods. This is equal to 100 years' life at the present rate of output—with possibilities of additional hundreds of millions if not billions of tons which may become available if costs can be reduced to the present level of those of the Utah Copper Company now operating profitably on 1% ore. This ore body together with certain others constitutes a very large reserve of copper. These occurrences do not include all the deposits of copper amenable to even the present methods of exploitation to say nothing of the known deposits certain to be developed through future economies. Similar considerations apply to the still more recent developments in Africa where one company already estimates its reserves at approximately 85,000,000 tons of ore averaging 6.87% copper. The existence of ore of this

grade is this a further best evidence of the presence of greater amounts of copper contained in ore carrying only 1% or less which upon the development of adequate transportation and labour supply will eventually become commercially available.

To summarize the situation as to the world reserves of copper in the so called porphyry deposits which although known were unavailable at the beginning of this century these deposits are now supplying one half the world's needs and have resources sufficient to last 10 years at the present rate of production with present method. The vein mines in the United States have in the past supplied over 65% of the output and may long maintain this proportion. At least we might estimate that their present resources are as great as those of the porphyry group. The American Bureau of Metal Statistics has published consumption figures showing clearly the relatively slow recovery of the European industry since the World War compared to the marked progress in the United States. At the same time the figures point definitely to an increasing European demand for the metal. Great Britain France and Germany have an aggregate population of 150,000,000 people. If their per capita requirements eventually reach the present level of those in the United States (15.54 for 1916) they will require an additional one and one quarter billion pounds of the metal per annum. On the other hand the existing facilities for production plus those in process of development and projected are sufficient to meet these requirements within the next ten years if they are needed. There is nothing to indicate any present failure of the supply of copper. Copper is practically indestructible and as the total supply of metal above ground increases the amount of second hand metal or scrap available for consumption increases and the need for virgin copper from the ground decreases.

(A. Not)

## IV. ALUMINIUM

The aluminum content of the earth appears to be concentrated near the earth's surface. F. W. Clarke and H. S. Washington estimate that the earth as a whole contains only 1.79% of aluminum but that the outer crust to a depth of 10 m contains 8.05%. This is equivalent to an aluminum oxide content of 15 to 16%. The ores of aluminum are employed for the production of aluminum alumina aluminous abrasives cement aluminum chloride alum etc. From economic considerations those ores are employed which yield the maximum number of units of alumina per unit of cost. For this reason the pre-eminent ore is bauxite which contains 50 to 60% of alumina. The bulk of the world's aluminum is produced from alumina extracted from bauxite by digestion with caustic soda—the well known Bayer process. In 1929 about four tons of bauxite would produce a ton of aluminum. Bauxite of commercial grade is available in extensive deposits in Europe North and South America Asia and Africa but the bulk of the production comes from the first three of these continents. E. C. Eckel upon the assumption that the available bauxite per square mile of area is the same in other continents as in Europe has estimated the world's bauxite reserves as about 2,500 millions of tons. In 1928 the world's consumption of bauxite was only about 1,500,000 tons. Allowing for substantial annual increases in consumption therefore the world's supply will last a long time.

The aluminum industry was in 1928 using the purest bauxite particularly with respect to silica and much of the world's supply of bauxite is less desirable for the Bayer process. However there are other processes being developed which can handle lower grades. Among these are the electric furnace process of C. M. Hall as recently developed by Aluminum Company of America as well as the processes of Pedersen and Haglund. Other ores of aluminum particularly certain of the silicates are proving susceptible to treatment by processes now under development so that when they become economically important they can be utilized. This will still further extend the available supplies of aluminum ores. The consumption index of aluminum is increasing more rapidly than some of the older commonly used metals. Up to 1929 aluminum has competed principally with copper and other non-ferrous metals on a price per volume basis. With the greater realization however of the economic value of the lightness and strength of aluminum and the development of strong, light alloys, aluminum

[illegible]

in the Central Province. The

[illegible]

In course of the world are generally—and probably correctly—regarded as being more valuable than those of any of the other major industrial metals and their extraction necessarily increasing with attendant price incentive to be considered. If the market price ever drops to a point where lower grade will be more profitable. Likewise economic to be effected in mining and higher recovery resulting from improved methods of extraction and processing will tend to expand the resource of the world. Still another factor is the possibility of discovering new fields of substantial importance the most likely area being interior Africa with French Indo-China, Siam and China offering excellent opportunity. In 1906 some authorities forecast a fairly uniform rate of production for ten years to be followed by a gradual decline because of the exhaustion of the producing fields. To day even the more apprehensive forecast supplies to assure any reasonable demand for a substantially longer period.

For a number of years the Federated Malay States have contributed about one third of the world's output of about 150 000 tons almost entirely from placer operation. In 1928 as a consequence of the putting into operation a large number of new modern dredges the percentage was increased to about 40 of the world total at the same time passing 1,000 000 tons. Still further increases in the Malay States are to be expected and with the introduction of bigger and better dredge the resources of exploitable grade are steadily expanding. Bolivia was the next largest producer in 1928 with 5% of the world's total compared with about 5% in recent years. Production comes from lode mines mostly in one district. The largest individual producer is planning a substantial expansion in production. Placers are being developed that may augment the output. Improvements in ore dressing and metallurgy are likely to make practicable the winning of lower grade lode ores of which there are good supplies. The Dutch East Indies third largest contributor account for about a quarter of the world's supply. The mines are placers and, being controlled by the Government no expansion in output took place in 1928. Nigeria Siam and China each with about 5% of the world's total output have fields possessing possibilities of expansion and a reasonably long life. (A B P)

## VIII TUNGSTEN

The metal tungsten has played a very important part within the last quarter of a century in the progress of the electrical and mechanical arts. Recent developments indicate that its importance will be still greater in the coming years. It is a chief component of tool steels and enters into the manufacture of heat resisting and non corrosive steels. Recently tools have been invented consisting of pure tungsten carbide imbedded in a metallic matrix which promise to revolutionize the art of cutting and shaping not only metals but also such unworkable materials as porcelain glass bakelite etc. In 1929 tungsten formed the light filaments contact points and X-ray targets of the electrical industry besides entering as a component into magnet steels. With the rapid strides made in radio and television its expansion into the electric industry may grow to huge proportions.

Nature has fortunately provided a very wide-spread mineralogical occurrence of tungsten both in the primary and secondary formations of the earth. The primary deposits are invariably

associated with granitoid rock and is not in ore. The secondary deposits form the principal source of the mineral in Occania and the Congo. In Australia, North and South America, Europe, Africa, and elsewhere, it has been commercially produced in only ten mineral. There has been a comparatively heavy demand and it has been the endeavour of producers of all kinds to supply as much as possible. The substitution of tungsten production has flowed from country to country as the surface ore was exhausted and more expensive deeper mining made necessary. Burma and the Federated Malay States held the bulk of the tungsten market until the World War. Then North and South America began to produce ore. China in 1917 produced only about 1% of the total output of the world whereas in 1929 it produced over 6%. From indications in 1929 the United States bid fair to become a large factor in tungsten mining as they are the largest consumer. Owing to its great importance in warfare it is the endeavour of the principal Governments of the world to keep their indigenous tungsten resources under development in spite of the lower cost of foreign minerals.

The important commercial mineral of tungsten fall under two main groups the first group being tungstates of the metals iron and manganese and the second group being the tungstate of calcium. The pure iron tungstate mineral is known as ferberite and the manganese tungstate as hubnerite. The mixed iron manganese tungstates are called wolframite. The only important mineral of the second group is the calcium tungstate known as scheelite. Until recently scheelite was the more coveted mineral for metallurgical purposes owing to its greater purity but progress in smelting and reduction practice has offset this advantage.

#### IX VANADIUM

The tremendous advances made within the last few years in the transportation industry be it railroad, automobile or aeroplane have very markedly brought forth the importance of the metal vanadium. It is always used in the metallurgical industry as an alloy. It is added to metals in very small quantities yet produces in the finished metal very marked changes in physical properties. The present day mass production in the automotive industry or the developments in the aeroplane motor would not have been possible had it not been for the development of vanadium metallurgy. Vanadium has also played an important part in armaments.

Vanadium is one of the most widely distributed elements in the earth's crust being present in almost all igneous rocks. However occurrences of the metal in concentrated mineral deposits are scarce. The one dominating occurrence of vanadium is at Minas Ragra in Peru, South America, being the source of 85% to 90% of the total vanadium produced in the world. The other workable deposits of vanadium have up to now also been confined to the Western Hemisphere in Mexico and the western parts of the United States especially the States of Colorado and Utah. Very recently however deposits containing vanadium have been developed on the African continent in Rhodesia and in the territory formerly known as German South West Africa and now under British mandate. There are other less important occurrences of vanadium known on the European continent in the iron ores of Sweden and Norway and also in those of Luxembourg. However these have no commercial significance. The mineral found in the most important deposit in Peru is patronite, a vanadium sulphide. In Colorado and Utah the occurring minerals are roscoelite, a vanadium silicate and carnotite, a radium bearing uranium vanadate. The ores of Mexico and Africa are descloizite and mottramite, complex vanadates of lead, zinc and copper.

The already known resources of vanadium minerals in the world fully assure an adequate supply for approximately the next 35 years. At the same time considerable effort is directed towards finding new deposits or further exploiting the known ones. The consumption of vanadium is augmenting yearly. Vanadium is an essential constituent of high speed tool steel, the demand for which has increased tremendously with the expansion of mechanical production. It is also used in heat resisting and non-corrosive steels. Very recently developments in the chemical industry will

tend to make large demands on vanadium resources. Vanadium is beginning to be used in the textile, varnish, linoleum and rubber industries and a particularly important application seems to be the use of it as a catalyzer in the manufacture of sulphuric acid replacing platinum. Vanadium may also be applied in the agricultural and pharmaceutical industries. Marked strides have been made in the metallurgical treatment of vanadium minerals so that material previously considered low grade or useless have been made available to the industry thus augmenting the sources of raw materials and thus adding to vanadium reserves. (B. D. S.)

#### X SULPHUR

Native sulphur or brimstone occurs in many places throughout the world generally either in beds of gypsum, limestone and associated rocks or in the vicinity of active and extinct volcanoes. The principal extensive deposits are found along the Gulf coastal plain of the United States in two places in Sicily at several points on the mainland of Italy in Japan, Spain, Austria, in the Aleutian Islands, Alaska, in the Chilean Andes, South America, in China, India, Russia and in several of the South Sea Islands. Until 1905 Sicily controlled the sulphur industry approximately 85% of the total world's supply being produced in Sicily and Italy.

It was discovered many years ago when drilling for oil that sulphur existed in large quantities in the saline dome formations of the Gulf coastal plain of the U.S. No successful method was devised for winning this sulphur until the development of the Frasch process about 1900. (See SULPHUR.)

With sulphur obtained at low cost by this process the deposits of Louisiana and Texas became the principal sources for the world. The Sicilian production taking second place. Since 1923 about 85% of the world's supply has been from the Texas field, 1% from Sicily and 5% from Japan, Spain and other countries.

It is estimated that the Texas known reserves are at least 50,000,000 tons. That more discoveries will be made is almost assured. The world's consumption of native sulphur since 1923 has averaged yearly about 2,300,000 metric tons. No recent data have been published regarding the reserves in Sicily. It is therefore to be seen that the supply will apparently be adequate for many years. Other deposits in the United States are of considerable extent but are not of present day commercial value. Pyrite, ores, gypsum and waste smelter gases may be considered sources of sulphur competing with native sulphur.

The chief use for native sulphur is to burn it to sulphur dioxide gas for the manufacture of sulphuric acid or for the production of sulphite liquors for paper pulp manufacture. For certain chemical purposes especially for the production of agricultural insecticide sprays and in the manufacture of rubber and sulphuretted products, native sulphur has a distinct field of use. (A. E. W.)

#### XI MERCURY

Although free mercury is found in the form of amalgams and approximately 50 ores containing mercury are known, cinnabar is the only ore found in sufficient quantity to be of commercial importance. It is rarely found in a high degree of purity but is always mixed with large quantities of rock. Italy and Spain (1929) furnish over 80% of the world's mercury. Nearly all of Italy's production comes from the Idria and Monte Amiata districts. In Idria the ore is rapidly approaching exhaustion but in Monte Amiata the quantity of reserves now under development is estimated at 20,000 metric tons, indicating a life of ten years at the 1929 rate of production and is supplemented by large undeveloped areas in the same region which insure a supply for a much longer time. In the Almaden district which furnishes the bulk of the Spanish supply the reserve is estimated at 40,000 metric tons or more assuring a supply for 25 years. The United States holds third place in production but the richest fields are fully or nearly exhausted and a thorough survey has revealed no important possibilities. Production in Czechoslovakia and Russia has increased each reaching 2% of the total. Mexico supplies about 1% of the total and the rest of the world less than 1%.

Production in the principal fields of Italy and Spain is regulated by agreement. The principal uses for mercury are (1)

drug and chemical ( ) luminous in appearance, and is used in lamps for pain's including various other uses in the electrical apparatus including radio tubes ( ) felt for its (6) mercury vapor lamps. The use of mercury has been almost entirely replaced by the use of silver and the amalgamation of gold and silver once important has been replaced by cyanide and flotation processes. The use of enamel is increasing.

## XII. SILICON

While the element silicon does not occur in the free state, its compounds make up approximately 25% of the earth's crust. Silicon is found in the form of silicon dioxide (silica) or as silicates generally in combination with aluminum (feldspar, etc.). Industrially useful and commercially important silicious resources are consequently generally found in these countries. Of primary importance are hydrous aluminous silicates broadly termed clays varying in purity of chemical composition and in physical properties from kaolin which yields the pure aluminum silicate kaolinite to the shales which contain enough kaolinite to render them workable in ceramic processes. The uses which clays find in industry may be summarized as follows: *kaolins* (white burning clays of high purity) for making paper, porcelain and chinaware, electrical porcelain, wall tile and rubber; *fire clays* (high fusing clays generally with some iron silica and 1 or 2% of iron lime and alkali) for fire brick and other metallurgical refractories, glass house refractories, gas retorts and retorts for zinc smelting and in general for use with high temperatures; sewer pipes, chimney tiles, clay and graphite crucibles and in the manufacture of aluminum sulphate; *common clays* and *shales* (miscellaneous rocks which become plastic on grinding in water) for common brick, sewer pipes, building tiles, portland cement, electrical conduit tiles, chemical stoneware.

*Silica* (silicon dioxide) occurs chiefly as quartz in the form of sand, sandstone, quartzite, rock vein quartz and rock crystal and also as infusorial earth. Quartz sand and crushed quartzite rocks find uses in abrasives, glass, glazes and enamels. Silica refractories, electric furnace products (silicon carbide and many metal silicon alloys), porcelains, sand lime brick and other ceramic products. Vein quartz or rock crystal is necessary for the production of transparent fused silica, but the translucent material may be made from quartz sand. Rock crystal in large sizes is important as a gem. Gannister, a form of quartzite is employed in manufacturing silica refractories. *Infusorial earth* or diatomaceous earth is employed for thermal insulation and for filtering and clarifying in chemical manufacture and fullers earth which is properly a clay is similarly used for bleaching and clarifying oils and fats. Among the useful silicate minerals is feldspar of primary importance in porcelain, whiteware and other ceramic products, glazes, enamels and glass. The minerals sillimanite, andalusite and kyanite are important raw materials for electrical insulators and also for greatly improved metallurgical refractories. *Asbestos*, a hydrous magnesium silicate (chrysotile) is woven into fire resisting fabrics and for brake linings and the shorter fibres are used in shingles and roofing sheets, coverings for the insulation of steam pipes and for parts of electrical equipment. *Talc* and *mica* are also important. (E. W. T.)

## XIII. MICA

The commercial importance of mica is due to its highly developed cleavage which permits the manufacture of dimensioned parts with great accuracy, its transparency, flexibility, stability at high temperatures and insulating qualities. No satisfactory substitute is known nor has any medium developed which can replace mica in modern electrical equipment. Mica is an essential constituent in the ignition system of the internal combustion motor and therefore of great importance in the automobile and aeroplane industries. The rapid development of wireless communication has also been dependent upon abundant supply of high grade mica. Mica production is restricted to the ancient stable land masses such as the peninsula of India, central and southern Africa, Madagascar, the Appalachian area in North America and the eastern areas in South America.

## PRECIOUS METALS GROUP

### PLATINUM METALS

After the World War of the world's supply of platinum metals came from under the mountains of the Rand district in the Transvaal, South Africa. The platinum group metals have been found in the Chocoma and other localities in South America. The Rand district is the largest source of supply during the World War and has continued important. Nickel-copper ores have been an important source of platinum metals when electrolytic refining was started on a large scale in 1910 by the International Nickel Company and the Mond Nickel Company, both of which operated mines in the Sudbury district of Ontario, Canada. The platinum metal has been produced in various provinces of Australia and Tasmania was for many years the largest producer of osmium. In 1910 osmium was first recovered as a by-product from the treatment of gold ore and tailings in South Africa, still the only reliable source.

Various other countries have yielded small quantities of the platinum metals but are not important sources of supply. In 1953 discovery of platinum group metals was made in certain basic igneous rocks in the Rand district of South Africa. Development of these deposits over the last two years has demonstrated the importance of this field. A small production of the metal was made during experimental work on the complex metallurgical problem which must yet be satisfactorily solved if the relatively low grade platinum metal bearing copper-nickel ores are to compete successfully with the placer fields of Russia and Colombia. Remelted or refined scrap platinum metals form a very important part of the yearly supply of the noble metal; the total recovered in 1914 in the United States alone was 35,000 troy ounces.

**Africa**—So long as the mines of the Transvaal continue their system of treating the blanket gold ores on corduroy or similar tables, there should continue to be produced at least 5,000 oz. of osmium a year. In 1914 there was discovered in the Transvaal what appears to be one of the largest and most important sources of platinum metals in the world. The deposits are in lodes and pipe form. The development so far accomplished has shown very large reserves of ore carrying 4 to 6 dwt. of platinum metals a ton. The metallurgy is complex and up to 1918 had not been satisfactorily solved. There is an immense reserve of platinum metals in the South African deposits which will eventually be available for consumption. It is reported that platinum has been discovered in alluvial deposits covering an area of at least 40 sq. m. in Sierra Leone north of the Gulf of Guinea.

**Australasia**—Platinum occurs with gold, tin and monazite in beach sands on the north-eastern coast of New South Wales at the mouths of Clarence and Richmond rivers. Apparently the production from this source has been small. Platinum has also been found in some masses of ironstone at Darling Creek and Mulga Springs near Broken Hill. Most of the platinum produced in New South Wales has come from alluvial washings at Fifield and Platina. Of late years the production from this district has been greatly diminished. Some quantities of platinum are known to occur with tin, monazite and gold in the beach sands at the south-eastern border of Queensland. So far as can be learned little platinum has been saved from these deposits. There are osmium fields 20 m. west of Waratah, Tasmania, on Nineteen Mile Creek, a tributary of Savage River. The Adams River field in west-central Tasmania was discovered in 1925 but was largely worked out by 1927. Papua, the south-eastern part of New Guinea has

produced a little osmium from placer deposits in the Waini and Arkora rivers on the south side of the Sanku river.

**Japan**—Osmium and platinum are obtained in the chief and cinnamon occur in the placer of Aibari, Iva, Aemai, and Uotanni rivers in the central and northern part of Hokkaido. A small yearly production has been made.

**Europe**—About 95% of the platinum in the world has come from the district on the European and on the Asiatic side of the Ural mountains of Russia. The platinum is washed from creek and river gravel from localities eroded from masses of peridotite and porphyry. To a considerable extent the production is still obtained from small hand workings, but recently large electric crushers have been installed which are able to handle poorer grades of materials. The average yield is said to be about 100 oz of platinum per metric ton of gravel. Frotsor Lopok estimates that there are reserves of 1,000,000 oz of platinum in Russia.

**North America**—Several creeks including Dine creek on Seward peninsula and some tributaries of Copper river in south central Alaska have yielded a little placer platinum but cannot be considered as source of regular supplies. The chief source of platinum metals in Canada is in the nickel copper ores of the Sudbury district of Ontario. These deposits are extremely large and in strong hard and should continue a regular producers of platinum metals for many years to come. The Tulameen river in southern British Columbia has been the source of a small yearly production of crude placer platinum. Most of the gravels have been worked several times and the district holds little promise for the future. In the United States the principal production of crude platinum has come as a by-product of gold dredging on the east side of the Sacramento and San Joaquin river valleys in California though a minor quantity of metal has been saved on Cottonwood creek in Shasta county, Hayfork creek in Trinity county, Calif., the Illinois river in Josephine county, Ore., and from the beach sands at various places from Eureka, Calif., north to the mouth of the Columbia river, Ore. The production in recent years has been declining and with the exhaustion of known dredging ground by about 1938 the output will be very small. A small quantity of palladium nickel copper ore has been produced from mines on Prince of Wales island, south east Alaska, near Good springs, Nevada, and Albany, Wyoming.

**South America**—Platinum was first discovered and described in material from Colombia and in 1788 the metal was being largely used in jewellery and in the manufacture of crucibles. At the end of 1788 there had been collected from Choco 3,820 Spanish pounds of the metal. In 184 the annual production from Choco is said to have amounted to about 1,000 pounds. The gold-platinum alluvial deposits of Colombia cover an area of more than 5,000 sq m, which lies west of the central ridge of the Colombian Andes in the Atrato and San Juan drainage basins and extends south of the mouth of San Juan river along the coast to Mira river. The richest deposits and those most worked are near the headwater of San Juan river principally on Condoto river. In the gravels of the San Juan drainage there are about equal quantities of gold and platinum but in the Atrato basin platinum constitutes approximately 15% of the value, the remainder being gold. The most productive area is held by American companies. What appears to be a conservative estimate gives a total of 536,000,000 cu yd of gravel that can be considered as reserves with 68,000,000 cu yd as proved ground capable of producing at a profit under present working conditions. This estimate of reserves may be increased in the light of future work.

**Uses of Platinum Metals.**—The essential uses of these metals are in the chemical, electrical and dental industries. Pure platinum is required in the chemical industry for catalyzers in the manufacture of sulphuric acid by the contact process and in the manufacture of nitric acid from ammonia. Pure platinum utensils of various kinds including crucibles, dishes, tongs and triangles, are required in every chemical laboratory. Platinum-iridium alloys containing from 15 to 50% iridium have been used very extensively by the electrical industry, but several satisfactory substitutes have been developed. Tungsten, molybdenum and nickel-chromium alloys are the principal substitutes but their use has

not done away with the need for platinum in the industry. The principal use of platinum-iridium alloy in electrical work is in the contacts and the proportion of iridium necessary in the alloy is directly dependent on the intensity of the current passing through the contacts and the speed at which the contacts move.

The chemical industry in the United States since 1918 has used between 1 and 2% of the platinum metals consumed and it uses relatively little except platinum. The dental industry uses approximately 14% of the yearly consumption of platinum metals and uses nearly equal quantities of platinum and palladium with relatively little iridium. Its use of platinum has decreased and of palladium has increased since 1915. The electrical industry normally consumes from 13 to 19% of the United States total of platinum metals using 1 times as much platinum as palladium and eight to ten times as much platinum as iridium. There is an increase in demand for iridium with the development of aeronautic internal combustion engines. The jewellery industry is the largest market for platinum group metals absorbing from 57 to 65% of the yearly turnover. It normally uses about 40 oz of platinum to one oz of iridium but since 1915 has been consuming more palladium and the minor metals of the platinum group including rhodium and osmium. The miscellaneous uses of platinum include the photographic chemical industry as the largest consumer and the gold pen industry which uses either the natural osmium or in recent years a synthetic osmium-iridium alloy which is said to be a satisfactory substitute for the native point metal.

The metals of the platinum group are essential to three important industries yet these three take only about one third of the yearly total. The jewellers take approximately the remaining two thirds and are the stable market for the noble metals. Stated in another way the platinum metals are essentially luxury metals and their continued demand on a large scale depends more on style in jewellery than on any other factor. Platinum jewellery can be made in more intricate design with equal strength than in other metals according to the makers and sets off gems and the costume as no other metal can. It would appear that the known reserves of platinum group metals in Russia, Colombia and South Africa are sufficiently large to supply world demand for many years to come with the possible exception of a supply of iridium. Iridium is an essential constituent of all hard platinum. Its chief source is from the natural alloy osmium-iridium and this alloy is extremely rare. Had it not been for a change in practice in South Africa for the treatment of the gold ores of the Rand in 1921 there would have been a serious world shortage of iridium.

(J. M. H.)

#### GOLD

Since the rise of the Spanish empire in the New World £4,245,000,000 of gold has been produced. Only 15% of this amount was produced between 1493 and the Californian alluvial discoveries of 1848 and over half in the first 27 years of the present century.

Of the total gold produced since 1493 the Transvaal has contributed 22%, the United States 21½% and Australasia 17%. The following table shows the value of the production in different areas—

Locality	Total amount	Amount produced in 1912-27
	£	£
United States (practically since 1849)	911,000,000	220,000,000
Transvaal (since 1884)	920,000,000	604,000,000
Australasia (since 1851)	715,000,000	98,000,000
Russia and Siberia (since 1814)	3,800,000,000	48,000,000
Mexico (since 1521)	146,000,000	46,000,000
Canada (since 1858)	132,000,000	74,000,000
India (since 1880)	70,000,000	32,000,000
Rhodesia (since 1898)	66,000,000	46,000,000
West Africa (since 1880)	28,000,000	19,000,000
South America, etc. (since 1493)	3,750,000,000	1,187,000,000
	869,000,000	1,128,000,000
Total 435 years	4,245,000,000	2,315,000,000

25,000,000 in 1930 and then declined to 10,000,000 in 1940 unless some new sources are developed (J. K. R.)

### SILVER

Any attempt to evaluate the world's resources in silver is complicated by the fact that silver is produced in connection with other metals, notably lead, copper and gold. Almost every gold mine produces some silver and every silver mine some gold. The three largest silver producing areas of the United States are Utah, Montana and Idaho in the first two which produce chiefly in connection with copper and in the latter in connection with lead ores. About one third of the silver in the United States is derived from what are primarily copper ore, one third from lead ores and the remainder from all other kinds including those which are simply silver ore. The silver content of most of the ores is so low that they could not possibly be worked for silver alone so that an evaluation of silver resources becomes an estimation of the resources of copper, lead, zinc or other deposits which are important producers of silver.

Silver occurs in rocks of all geological ages from the oldest to the most recent. It also occurs in nearly all countries of the world so that nearly all of them are able to produce at least some part of their requirements. China, however, which is one of the principal silver consuming countries of the world produces very little silver and it is not understood where its silver supply was obtained during its long isolation from the rest of the world. The available evidence as to the silver production of the countries with which it maintained contact does not indicate probable sources of supply. The Comstock lode in Nevada was discovered in 1858. By 1877 its annual production had reached \$1,000,000 in silver and for a long period this deposit furnished half the silver output of the United States, its total output of silver to 1900 being estimated at \$10,000,000. Its output since 1886 when most of the deep mines in the lode were abandoned has been relatively small. With the decline of the Comstock district the Leadville district in Colorado took its place as the greatest silver district of the world. Silver production there reached its peak (over \$11,000,000) in 1881 followed by a gradual decline until 1907 since when it has remained at about \$1,000,000 annually. The silver production of Canada was about 5,000,000 oz per year until 1905, when the Cobalt district was discovered. In 1910-13 the output was over 3,000,000 oz per year. Eight years later it was about 13,000,000 oz, now it is over 20,000,000 annually. The average yearly production of the world for the period 1901- was 188,000,000 oz ranging from 165,000,000 to 6,000,000. Mexico produces about one third of the total, the United States about one fourth and Canada and South America each contribute about one tenth of the total production.

The principal use of silver is in coinage and the industrial arts. Photographic and chemical uses (which are the only ones in which silver may be said to be consumed) require an annual amount estimated at from 10,000,000 to 20,000,000 ounces. It is evident therefore that there are two reserves of silver: unmined ore and the accumulated stock of metal. It seems certain that the world can produce for a long period enough silver for the uses by which it is actually consumed. How long it can produce enough to supply needs for coinage and industrial arts depends not only on the discovery of new silver producing districts and the production of metals with which it is associated but also to the extent to which silver coins may be replaced with token coins made of other more abundant metals. It is quite possible also that other metals may be substituted for silver in its uses in the industrial arts since recent developments in the art of chromium plating and in the production of non-corrosive alloy steels make it possible to produce at a reasonable price metal articles that will not tarnish. It is possibly safe to imply that a silver producing district like Cobalt will not be discovered anywhere except perhaps in northern Canada or parts of Africa and Siberia that have not been sufficiently explored. Consequently the principal additional supplies of silver for future use are likely to be copper, lead, zinc and other metal deposits where the large tonnage involved may yield considerable quantities even though the amount per ton is small. However, the copper deposits of Africa which constitute the

largest addition to the reserves of that metal which have recently been developed contain no important silver reserves (T. T. R.)

### RARE ELEMENTS

Cobalt, molybdenum, titanium, tantalum, uranium and radium are treated here as representative of important classes of rare minerals and nickel, vanadium and tungsten properly termed rare metals are discussed separately above.

**Cobalt.**—Cobalt is found in small quantities in many places and in large quantities in few. Its chief ores are smaltite ( $\text{CoAs}$ ) and cobaltite ( $\text{CoAsS}$ ). It is closely associated with nickel in occurrence and has been found in meteorites and in a number of rare minerals but the resources naturally play no very important role. The chief supply (1940-6) has been as follows: Queensland, Australia furnishing about 100 tons of cobalt content in cobaltite concentrates; the Belgian Congo about 825 tons of cobalt content in copper-iron cobalt alloy; and Ontario, Canada about 50 tons of cobalt content in alloys and chemicals. Arsenic sulphide ore from Chili and cobalt bismuth nickel ores from Saxony, Germany have added a few tons more of cobalt content making a total of about 1,600-1,700 tons. During 1927 prospecting failed to reveal any new commercially important supplies though some few prospects were located in Queensland at Pola de Lena (Asturias) and in the Province of Leon. Shipments of ore from Cobalt, Ontario in that year were reported as 7,309 tons and of oxide metal and salts from the Union Minière du Haut Katanga as 350 tons. During the first nine months of 1928 the production from Ontario amounted to 460,995 lbs of oxides, salts and unseparated oxides. The principal source in Ontario is high grade silver ores and concentrates averaging 5%-10% cobalt. These deposits and those of Africa seem to give an assurance of adequate supply. Some cobalt ores have been found in Norway, Sweden, the Caucasus, New Caledonia and at Lancaster Gap, Pennsylvania, U.S.A. During the last few years no cobalt has been produced in the United States. Other minerals containing cobalt are the sulphides linnaeite and jarosite, the arsenides safflorite and skutterudite and the cobalt copper sulphide carrollite.

**Molybdenum.**—The chief sources of molybdenum are molybdenite ( $\text{MoS}$ ) and wulfenite ( $\text{PbMoO}_4$ ). Molybdenite ( $\text{FeO}_3 \cdot 3\text{MoO}_3 \cdot 7\text{H}_2\text{O}$ ) and paterite ( $\text{CoMoO}_4$ ) are important sources. Molybdenum is rather widely distributed having been found in Norway, Sweden, Finland, Saxony, France, Italy, Belgium, Spain, South Africa, Australia, New Zealand, Japan and Peru but in recent years Canada and the United States have led in production. Early supplies up to 1910 came chiefly from Queensland. By 1917 Canada was the largest producer but of late the United States has been well in the lead. The ore at Climax, Colorado carrying molybdenite and molybdenite was said in 1923 to be capable of producing 1,000 tons per day for 30 years and this ore contains 11 lbs of molybdenite per ton. In 1927 the United States was practically the only producer of molybdenum. Concentrates averaging 75%-88%  $\text{MoS}_2$  amounted approximately to 2,150,000 lbs. This came principally from Climax, Colorado and Sulphur, Gulch, New Mexico. Although the consumption of molybdenum is increasing the supply keeps well ahead of the demand and a very recent statement shows that the area developed at Climax contains over 4,000,000 tons of ore. The present (1940) production is 3,000,000 lbs of metallic molybdenum per annum. The recent considerable increase in the use of molybdenum has been due to its growing employment in machine and other steels where great toughness is desired.

**Tantalum.**—Tantalum is closely associated with columbium or niobium and is found widely distributed in many rare earth minerals of which samarskite and euxenite are perhaps best known. The chief sources however are the minerals columbite and tantalite, two minerals which are identical except for the relative amounts of tantalum and columbium present. The general symbol representing their composition is  $\text{FeMn}(\text{NbTa})_2\text{O}_6$  and in various samples the ratio between the iron and manganese and the tantalum and columbium differs. In general tantalite is high in tantalum and columbite in columbium. Some ores from Australia run as high as 50% to 70%  $\text{Ta}_2\text{O}_5$ . In the Black Hills of South Dakota and in Connecticut, U.S.A. ores have been

making tin can for packing various commodities. The principal use of tin cans is for preserved food. It is easily possible to preserve food in ceramic ware jars and many foods are sold in glass jars but the jars are heavier and can easily be broken. For most purposes the glass jar is not therefore a satisfactory substitute for the tin can but for specially selected fruit which are to be sold at a high price the glass jar is better because the more attractive appearance of the jar is part of the consideration which enables it to be sold at a higher price. The glass is or is not a satisfactory substitute for tin in connection with food preservation according to the special conditions attending its use.

Tin plate in addition to being used for cans is utilized for roofing purposes obviously glass could not be so used. Terne plate (an alloy of lead and tin) is however used for roofing but could not be used for food containers as the lead in the alloy produces toxic effects. Collapsible tubes made of tin are extensively used as containers for tooth paste, shaving cream and various other commodities of a creamy consistence. No satisfactory substitute for tin has been devised for this purpose. Tin foil is used as a wrapping for candy and chewing gum as a lining for boxes and cartons or cigarettes and for a variety of other purposes. Aluminium foil and lead foil are to a growing extent substitutes for this use but neither has the bright lustre of tin foil. Except for appearance paraffined paper would serve this use equally well. A variety of attractive transparent moisture proof and dust proof wrapping materials have been placed on the market recently and for some purposes they are much better than tin foil while for other uses they are inferior. Tin when alloyed with copper produces bronze which has a variety of uses that it best serves. For some of these uses silicon or manganese can be used as the addition agent to the copper but for others they are not satisfactory. When manufactured for transmission wire cadmium can be used with better results than other substances from the transmission standpoint although not from other considerations. Tin is also used in the alloys employed for bearings in machinery. These alloys are of great variety depending on the service required of them, and a discussion of possible substitutes would be exceedingly complex. Tin has a variety of chemical uses two of the most important being for making enamels and weighting silk. In both cases the use of substitutes is possible.

For tin therefore various things may be used as substitutes in its various uses with variable degrees of effectiveness, according to the circumstances of each case. No one can safely prophesy that research will not reveal some substitute that will give equally good service at equal or even less cost and on the other hand no one can safely prophesy that it will. The whole subject of substitutes is charged with uncertainty from its very nature. In the search for substitutes several general considerations must be maintained as objectives. The first is that the substitute should be more abundant than that which it replaces. Little advantage is gained if a sufficient supply of the substitute material is not available. A second is that the substitution should be real not fictitious, large quantities of power or of other materials should not be generally involved in making the substitution. Substitutes should if possible be locally available to avoid the burden of transportation cost and also to avoid the possibility of being dependent on foreign countries for a source of supply. Finally the substitute should not impose too heavy a task in changing the habits of consumers or the usual processes of plant operations.

The principal use of manganese is in connection with steel manufacture and for this purpose an alloy containing 80% manganese is usually employed. In America manganese ore of the desired quality has to be imported, domestic ores can be used to make a 20% alloy but less conveniently as the 20% alloy has to be added while molten, although solid lumps of the 80% alloy that can be employed are commonly used. Substitution of the lower grade alloy is made difficult by this consideration.

Substitutes for gasoline have been much discussed and alcohol is one of the various materials that have been proposed. It has the great advantage that it can be made from vegetable materials that are reproducible. Alcohol cannot, however be used effectively in an engine built to use gasoline, it needs one specially

designed for it. Its general use as a substitute would therefore involve not only the organizing of industry to produce and distribute the alcohol but also the replacement of over 10,000,000 gasoline engines. Another possible substitute is gasoline made from oil shale. To mine the shale required to produce any considerable part of the gasoline now used would require the setting up of a mining industry of approximately the same size as our present coal mining industry and this industry would have to be in regions that are now very sparsely inhabited because they are arid. Thus not only a shifting of population would be required but also the provision for water and food supply, housing and other facilities. The task is thus much more complex than the working out of a process whereby gasoline can be made from oil shale.

Substitution of one product for another not only involves the various considerations outlined above but often requires the finding of adequate markets for by products. Much has been said about the wastefulness of buying coal in its raw state and one of the principal subjects for research is the processing of coal to yield coke gas and a great variety of by products. The proportions of these various things that can be made are definitely fixed by chemical and engineering considerations but the markets for them are quite variable not only from day to day but over longer periods. The demand for gas may be greater than the demand for the coke produced or it may be less and these relations may shift from day to day or week to week. For a time it was difficult to find adequate outlet for the benzol made as a by product and it was chiefly used as a substitute for gasoline. However development of the nitro cellulose lacquers provided a large demand for benzol at an increased price and the present supply was in 1929 practically all used for this purpose.

The problems involved in considering substitutes for things which are the result of life processes are even more complex. Citing clothing as an example changes in human habits and considerations of style are extremely important. Only a few years ago wool and cotton were the principal materials from which articles of clothing were made but in recent years demands have been transferred so largely to silk and fur that the woollen and cotton textile industries have been seriously affected. Straw ribbon and other materials were formerly used extensively in making women's hats but now felt hats are almost universal. To what extent demands for materials may be affected by a change in styles which may be brought about by skilful advertising and merchandising is exceedingly difficult to prophesy. Such changes have some limits imposed by physical conditions thus wool is used for men's outer garments because they keep their shape better.

In food products the tendency has been steadily to increase the number, variety and quality over a long period of years with the result that people are now better nourished than at any previous period in human history. Fruit for example instead of being available to only the wealthier class outside the growing season is now a regular article of diet in almost every home all the year round. Its greater consumption it is believed has led to a decline in the per capita consumption of meat. Sugar and chocolate are also used much more extensively than formerly. These like most other food products seem capable of being produced in any amounts that are required. Chewing gum though not a food is however an example of an organic product for which it may be necessary to find a substitute as its increasing use bids fair to outstrip the present supply of chicle gum (the principal ingredient) which is the only gum that at the temperature of the mouth is neither too soft nor too hard and is also free from any objectionable flavour. Rubber illustrates the manner in which public concern over supply of raw materials varies. The demand for rubber was easily met until the introduction of the automobile forecast a great increase. This caused much concern for future supply and many chemists have worked to discover substitutes. The great increase in rubber production in Malaya shifted attention to schemes to maintain the price of the raw material in the face of production that had increased faster than consumption. If anything equally serviceable can be produced and sold at less cost it will be adopted but the world

A common unit of force among engineers is the weight of one pound by which is meant the force equivalent to the gravitational attraction of the earth on a mass of one pound. This unit obviously depends on gravity and since this varies with the latitude and height of the place of observation (*see* EARTH, FIGURE *or*) the force of one pound" of the engineer is not constant. Roughly it equals 32.17 poundals. A pressure is a force per unit area and can be measured in terms of the above units, for example, as lb wt per square foot. The standard atmosphere (corresponding to a barometric height of 760 cm) is often taken as a secondary unit, it is equal to 1.013 600 dynes per centimetre.

the work measured by force acting over a distance. The unit of work is the erg which is the energy expended when a force of one dyne acts over a distance of one centimetre (See ENERGY). This unit is too small for measuring the quantity of energy a so-called for the most part. For such purposes a unit ten million times as great as the erg is used. As we noticed in the case of units of force common life experience has led to the introduction of units dependent on gravitation and therefore no arbitrary but the common British practical unit of this class is the foot-pound in the metric system its congener is the kilogramme metre.

Power is the rate at which force does work. It is therefore expressed by units of energy per second. The metric unit in use is the watt being the rate equal to 1 joule per second. Larger units in practical use are kilowatt equal to 1000 watts, the corresponding energy unit being the kilowatt second and 3600 kilowatt seconds or 1 kilowatt hour called a Board of Trade unit (B.T.U.). This last is a unit of energy not power. In British engineering practice the common unit of power is the horse power (HP) which equals 330 foot pounds performed per second or 33 000 foot pounds per minute. Its equivalent in the metric system is taken as 746 watts.

**Units of Heat.**—In studying the phenomena of heat two measurable quantities immediately present themselves—(1) temperature and (2) quantity of heat. Three arbitrary scales are in use for measuring temperature (See THERMOMETRY) and each of these scales affords units suitable for the expression of temperature. On the Centigrade scale the unit termed a Centigrade degree is one hundredth of the interval between the temperature of water boiling under normal barometric pressure (760 mm of mercury) and that of melting ice. The Fahrenheit degree is one hundred and eightieth and the Reaumur degree is one eightieth of the same difference.

Empirical units of quantity of heat readily suggest themselves as the amount of heat necessary to heat a unit mass of any substance through unit temperature. In the metric system the unit termed a calorie is the quantity of heat required to raise a gramme of water through one degree Centigrade. This quantity however is not constant since the specific heat of water varies with temperature (See CALORIMETRY). In defining the calorie therefore the particular temperatures must be specified. Consequently there are several calories particularized by special designations—(1) gramme calorie the heat required to raise 1 gramme of water between 15°C and 17°C through 1°C (2) mean or average gramme calorie one hundredth of the total heat required to raise the temperature of 1 gramme of water from 0°C to 100°C. These units are thus related—1 common calorie = 0.987 mean calories = 0.992 zero calories. A unit in common use in thermo chemistry is the *greater calorie* which refers to one kilogramme of water and 1°C. In the British system the common unit termed the British Thermal Unit (B.Th.U.) is the amount of heat required to raise one pound of water through one degree Fahrenheit. A centigrade unit (C.H.U.) has also been introduced and is rapidly being adopted.

**Electrical Units.**—We are principally concerned in electrical work with three quantities called respectively electric current, electromotive force and resistance. These are related to one another by Ohm's law which states that the electric current in a circuit is directly as the electromotive force and inversely as the resistance when the current is unvarying and the temperature of the circuit constant. Hence if we choose units for two of these quantities the above law defines the unit for the third. Much discussion has taken place over this question. From the scientific standpoint the current and voltage are most readily defined in terms of forces. The ampere is defined as one tenth of that current which flowing in a circle of 1 cm radius exerts a force of  $2\pi$  dynes upon a unit magnetic pole placed at its centre. This unit pole is itself defined in terms of the mechanical force between two such poles so the ampere is made to depend on mechanical units. Again voltage  $\times$  current  $\times$  time is mechanical work and is expressed in terms of ergs or joules. Resistance is voltage divided by current and thus the corresponding unit of

resistance is defined. But for electric engineering (power and light) the choice is decided by the nature of the quantities themselves. Since resistance is a permanent quality of a substance it is possible to select a certain piece of wire or tube full of mercury and declare that its resistance shall be the unit of resistance and if the substance is permanent we shall possess an unalterable standard or unit of resistance. For these reasons the practical unit of resistance now called the international ohm has been selected as one of the above three practical electrical units.

It is known that there are two available methods for creating a standard or unit electric current. If an unvarying current is passed through a neutral solution of silver nitrate it decomposes or electrolyses it and deposits silver upon the negative pole or cathode of the electrolytic cell. According to Faraday's law and all subsequent experience the same current deposits in the same time the same mass of silver. Hence we may define the unit current by the mass of silver it can liberate per second. Again there is the method already described. Thirdly the unit of electromotive force may be defined as equal to the difference of potential between the ends of the unit of resistance when the unit of current flows in it.

Apart however from the relation of these electrical units to each other it has been found to be of great importance to establish a simple relation between the latter and the absolute mechanical units. Thus an electric current which is passed through a conductor dissipates its energy as heat and hence creates a certain quantity of heat per unit of time. Having chosen our units of energy and related unit of quantity of heat we must so choose the unit of current that when passed through the unit of resistance it shall dissipate 1 unit of energy in 1 unit of time.

**British Association Units.**—The founders of the modern system of practical electrical units were a committee appointed by the British Association in 1861 at the suggestion of Lord Kelvin which made its first report in 1862 at Cambridge (See *B.A. Report*). The five subsequent reports containing the results of the committee's work together with a large amount of most valuable matter on the subject of electric units were collected in a volume edited by Prof. Fleeming Jenkin in 1873 entitled *Reports of the Committee on Electrical Standards*. This committee continued to sit and report annually to the British Association since that date until 1912 the whole of the reports have since been reprinted in book form. It is to the labours of this committee acting in friendly correspondence with international committees that the present system of electrical measurements is due.

**Electrostatic and Electromagnetic Units.**—It has throughout been recognized that a second consistent system of electrical units is possible. The unit electrical charge (or quantity of electricity) can be based upon the force between two electric charges. Accordingly on the *electrostatic* system the unit of electric quantity is such that  $f = q^2 / (Kd^2)$  where  $q$  is the quantity of each of two equal charges,  $d$  is the distance between them and  $K$  is the dielectric constant (or specific inductive capacity) of the intervening medium that of air being taken as unity (See ELECTROSTATICS). The current is then defined as the amount that flows in unit time and the energy is specified in terms of ergs or joules. Hence the unit of resistance is defined by means of the equation  $\text{Energy} = RC^2t$ . The relation between the electromagnetic and electrostatic system of units is that the absolute EMU unit of current (i.e. 10 amperes) is equal to  $3 \times 10^{10}$  electrostatic units (See the various articles on ELECTRICITY).

**Practical Electric Units.**—The committee of the British Association charged with the duty of arranging a system of absolute and magnetic units settled also on a system of practical units of convenient magnitude and gave names to them as follows—

$10^9$ absolute electromagnetic units of resistance	= 1 ohm
$10^8$ units of electromotive force	= 1 volt
$\frac{1}{10}$ th of an unit of current	= 1 ampere
$\frac{1}{10}$ th of an unit of quantity	= 1 coulomb
$10^{-9}$ units of capacity	= 1 farad
$10^{-15}$ units of capacity	= 1 microfarad

Since it is well known that the unit of magnetic flux is not a rational unit, the CGS system of units is not a rational system. The unit of magnetic flux is the maxwell, which is equal to the product of the unit of magnetic field strength and the unit of area. The unit of magnetic field strength is the oersted, which is equal to the unit of current divided by the unit of length. The unit of area is the square centimetre. The unit of magnetic flux is therefore equal to the product of the unit of current and the unit of length. The unit of magnetic flux is therefore equal to the product of the unit of current and the unit of length. The unit of magnetic flux is therefore equal to the product of the unit of current and the unit of length.

An Electrical Congress was held in Chicago, U.S.A. in 1893 to consider the subject of international practical electrical units, and the result of a conference between scientific representatives of Great Britain, the United States, France, Germany, Italy, Mexico, Austria, Switzerland, Sweden and Prussia, North America, after deliberating for six days, was a unanimous agreement to recommend the following resolution as the definition of practical international unit. The resolution and definitions were confirmed at other conferences, and at the last one held in London in Oct. 1903 were finally adopted. It was agreed to take—

As a unit of resistance the *International Ohm* which is based upon the ohm equal to  $10^9$  units of resistance of the CGS system of electromagnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice  $14.451$  grammes in mass of a constant cross-sectional area and of the length of  $106.3$  cm.

As a unit of current the *International Ampere* which is one-tenth of the unit of current of the CGS system of electromagnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water deposits silver at the rate of  $0.00111800$  of a gramme per second.

As a unit of electromotive force the *International Volt* which is the electromotive force that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere. It is represented sufficiently well for practical purposes by  $\frac{1}{1.105}$  of the E.M.F. of a normal or saturated cadmium Weston cell at  $0^\circ\text{C}$  prepared in the manner described in a certain specification.

As a unit of quantity the *International Coulomb* which is the quantity of electricity transferred by a current of one international ampere in one second.

As the unit of capacity the *International Farad* which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity. (This unit is far too large for most purposes—one millionth of it is called a microfarad—even a millionth of this is more practical in certain modern applications—it might be called a micro-microfarad or a dimicrofarad on the analogy of the use of di- in chemical nomenclature.)

As a unit of work the *Joule* which is equal to  $10^7$  units of work in the CGS System, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampere in an international ohm.

As a unit of power the *Watt* which is equal to  $10^7$  units of power in the CGS System, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

As the unit of inductance the *Henry* which is the induction in a circuit when an electromotive force induced in this circuit is one international volt while the inducing current varies at the rate of one ampere per second.

**Rational System of Electrical Units.**—The above described practical system based on the CGS double system of theoretical units labours under several very great disadvantages. The practical system is derived from and connected with an abnormally

large unit of magnetic flux, and an abnormally small unit of magnetic field strength. The unit of magnetic flux is the maxwell, which is equal to the product of the unit of magnetic field strength and the unit of area. The unit of magnetic field strength is the oersted, which is equal to the unit of current divided by the unit of length. The unit of area is the square centimetre. The unit of magnetic flux is therefore equal to the product of the unit of current and the unit of length. The unit of magnetic flux is therefore equal to the product of the unit of current and the unit of length. The unit of magnetic flux is therefore equal to the product of the unit of current and the unit of length.

**Heaviside's Rational System.**—(1) In order to remove the difficulty of the CGS system of units, which is based on the unit of magnetic flux, Heaviside proposed a new system of units, according to which a unit of magnetic flux is defined as the flux density in a unit pole in the ratio of  $1/4\pi$  to the unit pole. The unit pole is defined as the pole of a sphere of radius  $r$  such that the magnetic force on the surface of this sphere is  $m/4\pi r^2$  unit, and this is therefore also the numerical value of the flux density. Hence the total magnetic flux through the surface of the sphere is

$$4\pi r^2 \times m/4\pi r^2 \text{ units} = m \text{ units}$$

and therefore the number which denotes the total magnetic flux coming out of the pole of strength  $m$  in rational units is also  $m$ .

It follows therefore that if the intensity of magnetization of the magnetic filament is  $I$  and the section is  $s$ , the total flux traversing the centre of the magnet is  $Is$  units, and that if the filament is an endless or poleless iron filament magnetized uniformly by a resultant external magnetic force  $H$ , the flux density will be expressed in rational units by the equation  $B = I + H$ . The physical meaning of this equation is that the flux per square centimetre in the iron is simply obtained by adding together the flux per square centimetre if the iron is supposed to be removed and the magnetization of the iron at that place.

A final question suggests itself. Do the systems of units founded directly upon mechanical quantities constitute finality, or can we proceed to make a further reduction in the number of primary quantities?

There are certain constants of nature which are fundamental, invariable and as far as we know of the same magnitude in all parts of the universe. One of these is the *mass* of the atom, say of hydrogen. Another is the *length* of a wave of light of particular refrangibility emitted by some atom, say one of the two yellow lines in the spectrum of sodium or one of the hydrogen lines. Also a *time* is fixed by the velocity of light in space which is according to the best measurement very close to  $3 \times 10^{10}$  cms. per sec. Another natural unit is the so-called *constant of gravitation*, or the force in dynes due to the attraction of two spherical masses each of 1 gramme with centres at a distance of 1 cm. Very approximately this is equal to  $648 \times 10^{10}$  dynes. Another natural electrical unit of great importance is the electric charge represented by 1 electron. (See ELECTRICITY.) This according to the latest determination is nearly  $3.4 \times 10^{10}$  electrostatic units of quantity on the CGS system. Hence 2930 million electrons are equal to 1 ES unit of quantity on the CGS system, and the quantity called 1 coulomb is equal to  $879 \times 10^{18}$  electrons. In round numbers  $9 \times 10^{18}$  electrons make 1 coulomb. The electron is nature's unit of electricity and is the charge carried by 1 hydrogen ion in electrolysis. (See CONDUCTION, ELECTRIC, sec. Liquids.) Accordingly a truly natural system of physical units

$H$  is any quantity no matter what representing some salient feature in the kind of subject dealt with it is allowed to have a slope of variable gradient in any of the three directions in

The vast multitude of facts and phenomena which can thus be treated by a differential equation, so that previously unsuspected consequences can be deduced is surely of high interest even to those whose education does not enable them to follow the details. The reason why they are so powerful in enabling latent facts to be brought to light is plain enough. It is because the actual proc-

ences at work are compactly, precisely and completely formulated in all their interactions by these equations, so that they embody the essence of the phenomenon, their solution and consequence can subsequently be worked out by the few who possess sufficient skill and insight. This method of procedure—from formula through solution to interpretation—is indeed the highest example of the advantage possessed and the power gained by those who have successfully attained the aim of all science: *per se cognoscere causas*.

### MODERN PHYSICS

So long as we are dealing with massive bodies or with great groups of particles the laws of dynamics based upon Newton's laws of motion and applied without any breach of continuity were sufficient and reigned supreme. This kind of dynamics dominated the 19th century but just at the end as a fitting prelude to the 20th century a number of discontinuities began to be discovered. The first discontinuity was indeed old viz. the atomic theory of matter and was only evaded by the fact that we inevitably dealt with great numbers of atoms. In the years 1897 to 1900 however Sir J. J. Thomson, elaborating some 18,9 experiments of Sir William Crookes in a partial vacuum, discovered and finally clinched the discontinuity of electricity in other words he realized the electron which had previously been only surmised rather vaguely by a few. Zeeman and Lorentz had just showed that electric charges were the agents really responsible for the generation of radiation, a fact further illustrated and enforced by Röntgen's discovery of X-rays. After their isolation electrons were weighed and measured by Thomson and found to possess the fundamental properties of matter. The nature of radiation as emitted by electrons was analysed and examined in precise detail by the spectroscope. Then another discontinuity was discovered by Max Planck for as soon as single atoms and their constituent particles were attended to a new discontinuity appeared apparently in radiation but rather in what turned out to be a quantity connected with the orbital revolutions of an electron akin to the sweeping out of equal areas which Kepler long ago had formulated for the planets and Bohr formulated his astronomical theory of the structure of the atom. So through various channels it was found that these fundamental electric units which were presumably structures in the ether lay at the root of matter itself and that matter was actually an electrical phenomenon. Discontinuities are natural and inevitable when dealing with individual minute particles—they were only masked in previous days because this minute treatment had not been attempted though a hint had been given in that direction by the failure of the kinetic theory of gases as ordinarily applied to explain the irregular movements of very small bodies exposed to molecular bombardment.

**The Theory of Relativity**—Then came the theory of relativity which adopted generalized and boldly formulated a number of vague but growing suspicions. In particular it postulated a universal and unalterable constitutional velocity in the ether now known as  $c$  which had been recognized in Clerk Maxwell's theory as of an electromagnetic nature but the nature of which is still unknown. This like Planck's constant  $h$  is found to enter into every department of physics not only conspicuously when minute bodies are dealt with but secretly throughout. All matter is moving through the ether so that the constitutional velocity  $c$  of that medium enters into and modifies even the Newtonian laws of motion thus giving a complexity which sometimes seems strange to ordinary or evolutionary experience and with a little ingenuity can be made to appear paradoxical. Many other results of high interest follow and the gravitational function of the medium shows signs of yielding to mathematical treatment.

The revolutionary outcome of all this is that the ether in its various forms of energy dominates modern physics though many prefer to avoid the term ether because of its 19th century associations and use the term space. The term used does not much matter. Faraday began the discovery that it is in space that the real phenomena occur. Every differential equation is an expression in space with its three dimensions and the other abstraction called time and some attempt has been made to unify

these two great abstractions by aid of the velocity  $c$ . This however is rather varying on metaphysics unless it is merely regarded as a legitimate convenience in calculation to deal with four similar variables instead of three and an odd one.

One definite outcome of the bold generalisations or challenges of relativity is that energy which since its conservation was established has always been recognised as protean in form now includes not electric charges alone but matter itself as one of its forms so that atoms of matter might be turned into other forms of energy if only we knew how. The idea already has some cosmological significance for it is believed by Jeans to be the cause or mechanism of the radiation of the sun and other stars. The atom of matter is electrically constituted—it is composed of equal amounts of positive and negative electricity in its normal condition. High temperature signifies great activity or immense speeds among the atoms. They can be dissociated or broken up by collision and their opposite ingredients may occasionally clash, lose their identity or at least their locality and pass quickly away as a quantum of radiation. The interior of stars is known to be at an exceedingly high temperature and accordingly their mass is believed to be gradually decreasing their matter dying and passing away as radiation into the depths of space. Whether there is ever or anywhere a recuperative action is at present unknown. When if ever such action is discovered—as is not unlikely—it will have a cosmological and philosophical bearing.

It is interesting as illustrating Newton's exceptional foresight and speculative skill that at the end of a discussion on the changes and interchanges of known forms of energy (though the term energy as a dominating physical term was not adopted till long afterwards) he should conclude thus: And among such various and strange transmutations why may not Nature change bodies into light and light into bodies?

**Interaction of Matter and Radiation**—Meanwhile strange reactions have been discovered between matter and radiation. Radiation is generated by electrons and accordingly itself suffers discontinuity. Maxwell calculated that it must exert pressure—it is now found to exert pressure after the same bombarding fashion as the molecules of a gas exert it. Radiation is generated and absorbed not continuously but in quanta and these quanta exert a bombarding action as if they were particles or corpuscles yet they must be waves because they exhibit interference and diffraction phenomena—a study of which in optics began with Newton himself. Wave quanta with extra high frequency of vibration are more efficient projectiles and eject such suitable electrons as they encounter with more energy than do those with a more ordinary rate of vibration. This connection between energy and frequency is a development of Planck's quantum which like much else is due to Einstein's bold and forcible conceptions. The outcome of all this is that the old barrier between the corpuscular theory and the wave theory is being removed. There is truth in both. High speed particles are accompanied by waves somewhat akin to the waves at the bows of a steamer and the apparently sharp distinction between a wave and a corpuscle is subject to a compromise which includes both.

We have long studied matter by means or by the aid of radiation or waves—we are now beginning to see that momentum which seemed a property of matter is possessed by waves and that the familiar thing which we call matter is after all a manifestation or localization of ether energy in a form not as yet completely known or understood. Ether energy—the one fundamental existence—seems to manifest itself alternatively or even as it would seem indiscriminately sometimes as what we might call a particle and sometimes as a wave. De Broglie seems to have initiated this idea which has been taken up and elaborated by Schrödinger and others. The result is that whereas we once thought that we knew a great deal about an electron its size and its speed we are now confronted with some uncertainty. It is all very well to speculate and theorize but all theories must be verified and brought to the test of experiment and experiment—even indirect observation—on this minute scale is barely possible.

The difficulty can easily be rendered intelligible. We have to use some physical means to examine the behaviour of anything. We

The difficulty of examining very small things is increased by perturbations introduced by our measuring instruments. This can be illustrated in a simple manner. To take the temperature of a hot bath is easy enough, but a troublesome trouble could be introduced if the thermometer were altered by the thermometer employed. It is in fact difficult to observe any very small quantity without introducing perturbations. Heisenberg has actually formulated a law of uncertainty in a singularly definite manner showing that Planck's quantum is involved. There is an uncertainty in the position of an electron and in uncertainty about its speed or momentum. The product of the two uncertainties is equal to Planck's constant  $h$ .

There are still more recent developments. Speculation is active the revolution is in progress and fresh discoveries are constantly being made. The whole constitutes an elaborate network of interlocking coincidences which must have a deep meaning when we can unravel the tangled skein. All we can do now is to hint at the structure that are being reached to realize that nothing like the last word has been spoken to wonder at the genius which has so greatly illumined and yet partly confused us and to have faith in the advent of a great generalization. (O. I. L.)

**PHYSICS, ARTICLES ON** The astonishing advances which the science of physics has made since the Eleventh Edition of the Encyclopedia Britannica was prepared have been met by a complete and drastic revision of the physics articles. How far the researches of the present century have changed the outlook is evidenced by the fact that the Eleventh Edition contains nothing on relativity, on atomic structure or on the quantum theory, three questions which dominate modern physics and influence every branch. Not only have articles by the highest authorities on the new topics been introduced and the less fundamental articles on older subjects been cut down in size in such a way as to make the balance accord with actuality but every article has been either completely rewritten or revised so as to make it part of a proportioned and organic body of information on modern physics.

The articles SCIENCE and PHYSICS give a general view of the scope of physics and its place among the sciences. The fundamental nature of space and time in the physical world and of gravitation is discussed under RELATIVITY and SPACE TIME while the history of the growth and another aspect of the nature of the relativity problem is given under ETHER. An account of experiments and observations which played a great part in preparing the way for relativity will be found under MICHELSON MORLEY EXPERIMENT and ABERRATION OF LIGHT. Measurements of the VELOCITY OF LIGHT the constancy of which is fundamental are described under the article so entitled. The historical experimental and theoretical aspects of the subject are thus all readily accessible.

The subject matter of physics can be broadly classed as matter and radiation. The physical nature of matter is expounded under KINETIC THEORY OF MATTER which deals mainly with gases. Supplementary to this article is BROWNIAN MOVEMENT. The transition from gas to liquid is handled from the general theoretical point of view in the article LIQUEFACTION OF GASES which also deals with technically important aspects of the subject. The mod

The present century has been characterized by the development of matter and radiation in terms of electric charge of matter and of radiation in terms of photons which comprises this field is well represented in the Encyclopedia. The art of electricity in the Encyclopedia of which an article is devoted. A vast body of work has been published and developed the electron theory is described under ELECTRICITY CONDUCTION OF GASES. The connecting link between matter and radiation is furnished by the nuclear theory of the atom which asserts that an atom consists of a minute positively charged massive nucleus surrounded by groupings of electrons in motion. The general nuclear theory is explained under ATOM. The properties of the nucleus and their profound consequences for physics and chemistry under NUCLEAR ISOTOPES and POSITIVE RAYS. TRA SMUTATION OF THE ELEMENTS presents another aspect of nuclear theory. RADIOACTIVITY is an article of first importance for the understanding of modern physics. The theory of emission of light and X-rays by an atom described under ATOM is based upon the QUANTUM THEORY discussed in a key article which leads up to the new developments known as wave mechanics. X-RAYS NATURE OF SPECTROSCOPY BAND SPECTRUM RESONANCE POTENTIALS THERMIONICS PHOTOELECTRICITY COMPTON EFFECT RAMAN EFFECT deal with the experimental and theoretical side of radiation phenomena which have a prominent place in atomic physics while WILSON CLOUD CHAMBER describes a method of experimenting on single atoms and electrons which has had far reaching results.

The general body of physics is dealt with under comprehensive articles devoted to the main conventional divisions—HEAT LIGHT SOUND ELECTRICITY MAGNETISM with important supplementary articles among which may be mentioned under heat THERMODYNAMICS CALORIMETRY THERMOMETRY under light OPTICS SPECTROSCOPY FLORESCENCE AND PHOSPHORESCENCE under electricity ELECTRICITY CONDUCTION OF ELECTROLYSIS Important instruments and their uses are described under CONDENSER MICROSCOPE MICROSCOPY MIRROR BINOCULAR INSTRUMENT INTERFEROMETER INSTRUMENTS ELECTRICAL ACCUMULATOR INDUCTION COIL COMPASS SELENIUM CELLS VACUUM

Applied physics is another aspect of the subject which receives full representation. The meteorological side is represented by ELECTRICITY ATMOSPHERIC and the geophysical by TERRESTRIAL MAGNETISM EARTH CURRENTS and GRAVITATION. Some of the chief heads under which the bearing of physics in everyday life and industry is described in detail are ACOUSTICS AERODYNAMICS ELECTRIC LAMPS AND VALVES MANUFACTURE OF ELECTRO MAGNET GRAMOPHONE LENS PHOTOGRAPHY PHOTOMETRY TELEGRAPH TELEPHONE TELEVISION X RAYS. *Applications of* Every aspect of wireless is included in the scheme. ELECTRIC WAVES deals with Hertz's original discovery and the subsequent laboratory developments. WIRELESS TELEGRAPHY deals in two divisions with the theoretical and practical aspect of the subject while THERMIONIC VALVE MICROPHONE, LOUD SPEAKER RADIO RECEIVER describe apparatus vital to BROADCASTING, all aspects of which are discussed under that title. (E N D A C A)

**PHYSICS IN MEDICINE** The science of physics concerns itself with energy in its various manifestations and the properties of matter and in consequence plays a part in medicine whose value and importance are ever increasing. It furnishes means of investigating the structure of the animal body and the functions of its members. It assists in the detection of abnormality

of the body is the only source of energy. According to the principle of conservation of energy—it is the heat evolved from the oxidation of food which provides the energy for the body. The heat evolved from the oxidation of food is the only source of energy for the body. The heat evolved from the oxidation of food is the only source of energy for the body.

Source of Bodily Energy.—To find the source of the energy for the body, the heat evolved from the oxidation of food is the only source of energy for the body. The heat evolved from the oxidation of food is the only source of energy for the body.

Source of Bodily Energy.—To find the source of the energy for the body, the heat evolved from the oxidation of food is the only source of energy for the body. The heat evolved from the oxidation of food is the only source of energy for the body. The heat evolved from the oxidation of food is the only source of energy for the body.

Not only does the principle of conservation of energy apply to the body as a whole it is also applicable to the units which go to form it. The energy changes and oxidations necessary for life which occur in the cell. Now the living cell consists of a watery solution containing colloids, crystalloids and substances in suspension enclosed in a cell wall or membrane. Therefore the study of the physical properties of solutions, colloids and membranes in the laboratory should and does afford much information concerning its behaviour. Below some of these properties are examined with this object.

Hydrogen Ion Concentration.—It is well known that solutions which conduct electricity (electrolytes) do so in virtue of the electrically charged ions, positive and negative derived from the dissociation of the molecules of the dissolved substances. Pure water is only slightly ionized, yielding hydrogen ions carrying a positive electrical charge and an equal number of hydroxyl ions with a negative charge. The product of the concentration of hydrogen ions and hydroxyl ions being constant for a given temperature. When a substance is dissolved in water it in general produces a change in its chemical neutrality owing to the disturbance in the balance existing between the concentration of hydrogen and hydroxyl ions. Thus an acid dissolved in water yields hydrogen ions as a direct result of solution and leads to an increase in hydrogen ion concentration and a decrease in the concentration of hydroxyl ions. Similarly the solution of a base produces hydroxyl ions and leads to a decrease in hydrogen ion concentration and an increase in the concentration of hydroxyl ions.

Acidity then is due to the preponderance of hydrogen ions over hydroxyl ions and alkalinity is due to the converse. Neutrality is an equilibrium of hydrogen and hydroxyl ions. Certain substances—called amphoteric electrolytes—produce both hydrogen ions and hydroxyl ions on dissociation and may therefore combine as acids with bases, or as bases with acids. Proteins are of this class and so of course is water.

An alteration in acidity is the causative factor in the regulation of respiration, the activity of muscle and the excitability of nerve and plays an important part in regulating excretion and secretion.

The powerful effects of variation in hydrogen ion concentration

on physiological processes require the existence of mechanism for the prevention of considerable changes of this kind. One of the main functions of blood is to provide this. It can itself with the addition of relatively considerable amounts of free acid or free alkali without much change in its reaction, largely owing to the presence of carbonates and phosphates. The electrolytic dissociation theory provides the only satisfactory explanation of this.

Colloids and Membranes.—The colloidal state is recognised as a permanent suspension of solid particles or liquid globules in a continuous medium of a different kind. In contrast to true solutions, colloids are heterogeneous systems in which the suspended particles are large enough to possess the special properties peculiar to surfaces. It is easily seen that since molecules at the surface of separation of two phases are attracted more powerfully in the direction of the phase to which they belong than in the opposite direction, the interface will be in a state of tension. Consequently any change in the area of a surface film will result in a loss or gain of surface energy. Again particles of colloid solution usually possess an electrical charge which is localized on its surface. Such particles are to a large extent prevented from aggregating together and falling as precipitates by the mutual repulsion of their electrical charges.

The deposition of charged ions on a colloidal particle or any surface would confer on the surface a charge of corresponding sign. This process is called *adsorption* and it may or may not be accompanied by chemical action between the constituents of the surface and the adsorbed material. The neutralization of electrical charges by adsorption of oppositely charged ions from added neutral salts results in precipitation. A similar effect may be produced by oppositely charged colloids.

An important case of adsorption is that occurring at the semi-permeable membrane which covers cells. Physical principles show that any material which lowers surface energy will be accumulated in the surface. Certain substances such as proteins may form solid deposits in the surface films owing to their concentration brought about in this way. These deposits are capable in some cases of being redissolved if carried into the interior of the cell. Hence the cell membrane must have a variable structure in equilibrium with its contents.

Osmotic Pressure.—Semi-permeable membranes, i.e. membranes which allow water to pass freely but hold back dissolved substances exhibit another important property. Water will tend to diffuse more rapidly through the membrane towards that side on which the concentration of dissolved substance is greater than in the reverse direction. This would cause a difference in hydrostatic pressure on the two sides if an increase in volume of the more concentrated solution is prevented by a non-yielding envelope. This pressure is called *osmotic pressure* and the unilateral passage of fluid *osmosis* ( $qv$ ). Solutions which exert the same osmotic pressure are said to be *isotonic*.

It is easy to see that the solutions which bathe a cell not enclosed in a rigid envelope must for equilibrium possess the same osmotic pressure as the cell contents. Otherwise the cell will contract through loss or expand through gain of water and will be destroyed unless the osmotic pressures can be equalized in this way. In any case if any change of concentration occurs the functional activity of the cell will be affected. The membrane covering individual cells and blood corpuscles is impermeable to salts, glucose, etc. that forming the walls of the capillary blood vessels is permeable to these but not to colloids.

The osmotic pressure of colloids although it is very small compared with that of solutions of electrolytes has been shown by Starling to play an important part in the formation of urine. Oedema also according to some authors is a phenomenon of osmosis.

The chemical behaviour of colloidal particles is very inert compared with the same amount of material in true solution. This permits of the use in medicine of colloidal preparations of metals and other powerful drugs to secure a slow and prolonged action of continuous minute doses of the active, ionized form into which they break down.

The refractive index of the medium in which the electrolyte and to one of the electrodes. The electrodes are placed in a solution of the electrolyte and when the voltage is applied, the current flows through the electrolyte and the electrodes.

**Physics of Muscle and Nerve**—The study of the physics of muscles and nerve illustrates the physical principles in a manner the dependence of mechanical properties on the dependence of the physical properties on the physical properties. The explanation of physiological phenomena has had the development of physical theory or the physical matter but also the invention and technical perfection of detecting and recording instrument of the great series of the heat precision.

In order to maintain living muscle and nerves outside the animal for long periods they are bathed in an artificial saline solution which as we have seen must be isotonic with them and have the same hydrogen ion concentration. Now much of the difficulty in investigating vital processes is due to the microscopic size of the living cell which results in changes which are also small. Largely owing to the development of sensitive galvanometers and also to the modern thermionic amplifier and cinematograph camera it is possible to detect extremely small variations of energy if they occur in the form of electrical change or can be converted into that form. Minute changes of temperature—and therefore the production of small quantities of heat—can be measured by the electrical currents generated in thermocouples or by changes in electrical resistance of metallic conductors.

**Methods of Investigation**—In studying the activity of an isolated nerve or muscle preparation it is usual to employ a brief electric current as stimulus since it is possible to repeat it without producing permanent damage and the duration and intensity can be so readily and accurately controlled. By these means it has been possible to measure with some accuracy the heat produced in a muscle by a single stimulus and also that liberated over long intervals at rest or in recovery after prolonged stimulation. The results prove that oxidation is necessary to maintain the normal life and structure of an animal cell in a living but completely resting condition. Further it has been shown that muscular contraction is a surface phenomenon since the energy developed is proportional to the length of the fibres and not their volume.

Similarly it has been shown that the nervous impulse is excited by a stimulus which in all probability consists in an accumulation of ions in certain parts of the nerve fibre. The arrival of the impulse at any point on the nerve is indicated by the active region developing a negative electrical potential with regard to the neighbouring inactive regions. If then electrodes are placed in contact with the active and inactive regions and connected through a galvanometer a current will pass through the circuit towards the active region. It is found that the energy involved in the transmission of the impulse is derived from that stored in the fibre itself and not from the stimulus; the latter only acts as a trigger.

**Radiation**—Not the least service rendered by physics to medicine is the demonstration and exploitation of the fact that in addition to those radiations—light and radiant heat—which are directly perceived through the senses there exist others which have a profound influence on the animal body. The spectrum of electromagnetic radiation is now known to comprise in descending order of wave lengths the Hertzian waves of wireless communication, infra red rays, the visible spectrum, ultra violet rays, X rays and the gamma rays of radio active substances. The shorter wave lengths of the visible spectrum and the still shorter ones mentioned above all possess the power of either stimulating or destroying the animal cell according as the quantity of energy absorbed is small or excessive. The action of the rays is selective in that different cells exhibit different degrees of response to a given quality and intensity of radiation.

Some radiations notably those from certain parts of the ultra violet spectrum have a specific action on biological material, i.e.,

the absorption of a given amount of radiant energy of this wave length produces a much greater response in a given cell or tissue than the absorption of an equal amount of energy of other wave lengths.

The selective action of the spectrum and the selective effects of the rays are of great importance in radiation therapy.

The selective action of the rays on the cell has not been fully explained. It is however attributed to the fact that the energy produced by the energy absorbed or to the ionization produced by the energy absorbed in the atoms of the cells involved. The physical method of measuring the dose measurement in radiation therapy is also determined by these two last mentioned properties. Exact dose measurements have shown that the biological effects produced by different kinds of radiation obey similar laws in that they all require a minimum duration and have a threshold value of intensity below which no effect is produced.

For other applications of physics to medicine the reader should consult the following articles—PHYSIOLOGY, HYGIENE, ELECTROTHERAPY, RAYS, RADIUM (F. H. D.).

**PHYSIOCRATIC SCHOOL**, the name of a group of French economists and philosopher. The heads of the school were François Quesnay (q.v.) and Jean Claude Marie Vincent, sieur de Gournay (1711–1759). The principle of the school had been put forward in 1755 by R. Cantillon, a French merchant of Irish extraction (*Essai sur la nature du commerce en général*) but it was Quesnay and Gournay who gave them a systematic form and made them the creed of a united group of thinkers and practical men bent on carrying them into action. The members of the group called themselves *les économistes* but it is more convenient because unambiguous to designate them by the name *physiocrates* (Gr. *physis* nature, and *kratein* to rule) invented by P. S. Dupont de Nemours (1739–1817).

The general political doctrine is as follows. Society is composed of a number of individuals all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities each can at least best understand his own interest and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each just so far as it is inconsistent with the rights of the others. Government though necessary is a necessary evil and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere this implies the right of the individual to such natural enjoyments as he can acquire by his labour. That labour therefore should be undisturbed and unfettered and its fruits should be guaranteed to the possessor in other words property should be sacred. Each citizen must be allowed to make the most of his labour and therefore freedom of exchange should be ensured and competition in the market should be unrestricted no monopolies or privileges being permitted to exist.

**The Single Tax on Land**—The physiocrats then proceed with the economic analysis thus. Only those labours are truly productive which add to the quantity of raw materials available for the purposes of man and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course metals) over their cost of production. On the amount of this *produit net* depends the well being of the community and the possibility of its advance in civilization. The manufacturer merely gives a new form to the materials extracted from the earth, the higher value of the object after it has passed through his hands only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another, what the trading classes gain thereby is acquired at the cost of the nation and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are 'useful' indeed but they are 'sterile' drawing their income, not

from a time when they had been a part of the super-  
 stitious and feudal system. The school of thought  
 which must be called the physiocratic school must  
 be said to have been a part of the great movement  
 of the 18th century for the reform of society.

The physiocratic doctrine relating to the exclusive production  
 of wealth by agriculture and commerce was founded in error.  
 And the proposal of a single *impôt territorial* to be levied  
 on the land was a measure of energy which the school  
 of thought which it represented did not hold. The  
 effective result of its teaching was mainly destructive. It  
 continued in a more systematic form the efforts in favour of the  
 freedom of industry already begun in France and in England.

**The Rule of Nature**—These conclusions as to the revolu-  
 tionary tendencies of the school are not at all affected by the  
 fact that the form of government preferred by Quesnay and  
 some of his chief followers was what they called a legal despotism  
 which should embrace within itself both the legislative and  
 the executive function. The reason for this preference was  
 that an enlightened central power could more promptly and  
 efficaciously introduce the policy they advocated than an assem-  
 bly representing divergent opinions and fettered by constitutional  
 checks and limitations. Turgot used the absolute power of the  
 Crown to carry into effect some of his measures for the liberation  
 of industry though he ultimately failed because unsustained by  
 the requisite force of character in Louis XVI. But what the  
 physiocratic idea with respect to the normal method of govern-  
 ment was appears from Quesnay's advice to the dauphin that  
 when he became king he should do nothing but let the laws  
 rule, the laws having been of course first brought into con-  
 formity with the *ius naturae*. The partiality of the school for  
 agriculture was in harmony with the sentiment in favour of  
 nature and primitive simplicity which then showed itself in so  
 many forms in France especially in combination with the revolu-  
 tionary spirit and of which Rousseau was the most eloquent  
 exponent. The members of the physiocratic group were un-  
 doubtedly men of thorough uprightness and inspired with a  
 sincere desire for the public good especially for the material  
 and moral elevation of the working classes. Quesnay was phy-  
 sician to Louis XV and resided in the palace at Versailles  
 but in the midst of that corrupt court he maintained his integrity  
 and spoke with manly frankness what he believed to be the  
 truth. And never did any statesman devote himself with greater  
 singleness of purpose or more earnest endeavour to the service  
 of his country than Turgot who was the principal practical rep-  
 resentative of the school.

The physiocratic school never obtained much direct popular  
 influence even in its native country though it strongly attracted  
 many of the more gifted and earnest minds. Its members writing  
 on dry subjects in an austere and often heavy style did not find  
 acceptance with a public which demanded before all things charm  
 of manner in those who addressed it. The physiocratic tenets  
 which were in fact partly erroneous were regarded by many  
 as chimerical and were ridiculed in the contemporary literature  
 as for example the *impôt unique* by Voltaire in his *L'Homme  
 aux quarante écus* which was directed in particular against P. P.  
 Mercier Lavière (1720-1794). It was justly objected to the  
 group that they were too absolute in their view of things they  
 supposed as Smith remarks in speaking of Quesnay that the  
 body politic could thrive only under one precise regime—that  
 namely which they recommended—and thought their doctrines  
 universally and immediately applicable in practice. They did  
 not as theorists sufficiently take into account national diversities  
 or different stages in social development nor did they as poli-  
 ticians adequately estimate the impediments which ignorance  
 prejudice and interested opposition present to enlightened states-  
 manship.

The physiocratic system after guiding in some degree the

policy of the Constituent assembly soon ceased to exist as a  
 living power but its good elements were incorporated into the  
 more complete construction of Adam Smith.

**PHYSIOGNOMY**, a term which denotes a supposed science  
 for the discovery of the disposition of the mind by the linea-  
 ments of the body (Bacon) is also used colloquially as a syno-  
 nym for the face or outward appearance being variously spelled  
 by the old writers.

Physiognomy was regarded by those who cultivated it as a two-  
 fold science (1) a mode of discriminating character by the out-  
 ward appearance and (2) a method of divination from form  
 and feature. On account of the abuses of the latter aspect of the  
 subject its practice was forbidden by the English law. By the act  
 of parliament 17 George II c. 5 (1743) all persons pretending to  
 have skill in physiognomy were deemed rogues and vagabonds  
 and were liable to be publicly whipped or sent to the house of  
 correction until next sessions. The pursuit thus stigmatized as  
 unlawful is one of great antiquity in ancient times physiognomy  
 was a profession.

The first systematic treatise which has come down to us is that  
 attributed to Aristotle in which he devotes six chapters to the  
 consideration of the method of study the general signs of char-  
 acter the particular appearances characteristic of the dispositions  
 of strength and weakness of genius and stupidity of timidity im-  
 pudence anger and their opposites etc. Then he studies the  
 physiognomy of the sexes and the characters derived from the  
 different features and from colour hair body limbs gait and  
 voice. He compares the varieties of mankind to animals the male  
 to the lion the female to the leopard. The general character of  
 the work may be gathered from the following specimen. While  
 discussing noses he says that those with thick bulbous ends belong  
 to persons who are insensitive swinish sharp tipped belong to the  
 irascible those easily provoked like dogs rounded large obtuse  
 noses to the magnanimous the lion like slender hooked noses to  
 the eagle like the noble but grasping round tipped retroussé  
 noses to the luxurious like barn-door fowl noses with a very  
 slight notch at the root belong to the impudent the crow like  
 while snub noses belong to persons of luxurious habits whom he  
 compares to deer open nostrils are signs of passion etc.

While the earlier classical physiognomy was chiefly descriptive  
 the later mediaeval authors particularly developed the predictive  
 and astrological side their treatises often digressing into chiro-  
 mancy onychomancy chiromancy podoscopy spasmatomancy  
 and other branches of prophetic folk lore and magic.

Along with the medical science of the period the Arabians con-  
 tributed to the literature of physiognomy notably Ali b. Ragel  
 Rhazes and Averroes. Avicenna also makes some acute physiog-  
 nomical remarks in his *De animalibus* which was translated by  
 Michael Scot about 1270. Among mediaeval writers Albertus Mag-  
 nus (born 1205) devotes much of the second section of his *De  
 animalibus* to physiognomy. The famous sage of Balwearie  
 Michael Scot while court astrologer to the emperor Frederick II  
 wrote his treatise *De hominis physiognomica* much of which is  
 physiological and of curious interest. It was probably composed  
 about 1272 but not printed until 1477. This was the first printed  
 work on the subject.

The 16th century was rich in publications on physiognomy.  
 Treatises were published among others by John de Indagine  
 Coclès Andreas Corvus Michael Blondus Janus Cornaro Anselm  
 Douxciel Pomperius Ronnseus Gratarolus Lucas Gauricus Tri-  
 cassus Cardanus Taismerus Magnus Hund Rothman Johannes  
 Padovanus and greatest of all, Giambattista della Porta. The  
 earliest English works were anonymous *On the Art of Foretelling  
 Future Events by Inspection of the Hand* (1504), and *A Pleasant*

*Introduction to the Art of Physiognomy and Expression* (1806) by Dr Thomas Hills's work *The Connection of Mind and Matter in Learning and Discovery in the Art of Physiognomy* published in 1811 a quaintly written adaptation from the Italian authors of the day.

The development of a more accurate anatomy in the 18th century seems to have diminished the interest in physiognomy by substituting fact to fiction and consequently the literature though as great in quantity became less valuable in quality. The principal writers of this age were T. Campinella, R. Loeckius, Clement Timpler, J. E. Galliard, Moldenhart, Septan, Saunders, C. Lebrun (a precursor of Charles Bell), Elphinstone, La Bellicre, J. Evelyn (in the appendix to *Vomismata*), Balducci, Bulwer (in his *Pathomyotomia*), Fuchs, Sponson, Garidel, Chiaventi, A. Ingegnieri, Finella, De la Chambre, Zanard, R. Faudé, and others of less importance.

The 18th century shows a still greater decline of interest; the only name worthy of note is that of J. K. Lavater (q.v.). The popular style, good illustrations and pious spirit of his works gave them a popularity they little deserved as there is no system in his work which chiefly consists of rhapsodical comments upon the several portraits.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, whose *Essay on the Anatomy of the Expression* published in 1806 was the first scientific study of the physical manifestation of emotions in the terms of the muscles which produce these manifestations. In the later editions of this essay the thesis is elaborated with greater detail. Moreau's edition of Lavater in 1807 was somewhat along the same lines. In 1817 Dr Cross of Glasgow wrote his defence of a scientific physiognomy based on general physiological principles. The experiments of G. B. A. Duchenne (*Mécanisme de la physiognomie humaine*, Paris, 1863) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These observations confirmed by experimental demonstration the hypothetical conclusions of Bell. The machinery of expression having thus been indicated the connection of the physical actions and the psychical state was made the subject of speculation by Herbert Spencer (*Psychology*, 1855). These speculations were reduced to a system by Darwin (*Expression of Emotions*, 1872) who formulated the following as fundamental physiognomical principles—

(1) Certain complex acts are of direct or indirect service under certain conditions of the mind in order to relieve or gratify certain sensations or desires and whenever the same states of mind are induced the same sets of actions tend to be performed even when they have ceased to be of use. (2) When a directly opposite state of mind is induced to one with which a definite action is correlated there is a strong and involuntary tendency to perform a reverse action. (3) When the sensorium is strongly excited nerve force is generated in excess and is transmitted in definite directions depending on the connections of nerve cells and on habit.

The last of these propositions is adversely criticized by P. Mantegazza as a truism but it may be allowed to stand with the qualification that we are ignorant concerning the nature of the influence called nerve force. It follows from these propositions that the expression of emotion is for the most part not under control of the will and that those striped muscles are the most expressive which are the least voluntary. To the foregoing may be added the following three additional propositions so as to form a more complete expression of a physiognomical philosophy—

(4) Certain muscles concerned in producing these skin folds become strengthened by habitual action and when the skin diminishes in elasticity and fulness with advancing age the wrinkles at right angles to the course of the muscular fibres become permanent. (5) To some extent habitual muscular action of this kind may by affecting local nutrition alter the contour of such bones and cartilages as are related to the muscles of expression. (6) If the mental disposition and proneness to action are inherited by children from their parents it may be that the facility in and disposition towards certain forms of expression are in like manner matters of heredity.

Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne and Darwin and in the later publications of Theodor Piderit *Mimiké und Physiognomik* (1886) and

Mantegazza *Physiognomy and Expression* (1890) to which the reader may refer for further information.

For material on art in anatomy as applied to physiognomy see the catalogue of the two authors by Ludwig Choulant *Galerie und Festschrift der anatomischen Gesellschaft zu Leipzig* and the work of the author enumerated above especially his article *Franz Peter Caspar Corvus and Bulwer For the relation of the face to the usual medical handbooks see* *Caution L'art de la physiognomie de la face dans les maladies* (Paris 1806) Mantegazza *Physiology of Pain* (1893) and Polli *Saggio di fisiologia e psicologia* (1893). For ethnological physiology see the *Journal of the Royal Anthropological Institute* and amongst moderns the *Journal of the Royal Anthropological Institute* especially the *Journal of the Royal Anthropological Institute* (1893) and Park Harrison *Journal of the Royal Anthropological Institute* (1893). **PHYSIOLOGICAL ARTICLES.** The special articles in Physiology form natural complements to those of the medical programme. DIGESTION, HEART AND CIRCULATION, NUTRITION, EYE, LIBRUM, MUSCLE AND MUSCULAR EXERCISE, PAIN, SIGNIFICANCE OF BIOCHEMISTRY, SMELL AND TASTE, ENZYMES AND REPRODUCTION AND SEX are among the most important articles in this section. See also MEDICAL ARTICLES.

**PHYSIOLOGY** is the science which treats of the functional working of the body in health as opposed on the one hand to anatomy which treats of the structure of the body and pathology which treats of its function as distorted by disease. In all forms of animal life except the lowest the body is made up of organs. With regard to the functions of all the more important organs special articles will be found under their respective names (see HEART, INTESTINE, LIVER, LUNG, etc.).

The activities of these organs are co-ordinated by the nervous system (see BRAIN, NERVE, SPINAL CORD, SYMPATHETIC SYSTEM) and the hormones (see HORMONES). Nevertheless the body is in a sense more than a number of co-ordinated units. The body has an architecture which has been evolved along well defined lines and which it is the business of the present article to trace as far as may be possible.

The phrase well defined lines rather than well defined principles has been used advisedly for it may often be a matter of speculation whether even when a frequent repetition of the same sort of architectural conceit occurs any principle is really involved or whether merely the same sort of accident has taken place in the same sort of way. To the most reflective type of mind physiology presents no more fascinating problem than that of the extent to which the structure of the body is the result of some well ordered plan either of evolution or design. In the strict sense of the word principle would imply such a plan but in what follows the word will be used more loosely to include phenomena that recur with sufficient frequency to simulate an orderly sequence even though the recurrence may in reality be little more than accidental.

**Constancy of Internal Environment.**—This principle is associated particularly with the name of the great French physiologist Claude Bernard. Innumerable examples might be given in illustration of it but a few must suffice. Moreover the examples might be either in the realm of the physical or of the chemical properties of the environment. The first to be discussed namely constancy of internal temperature is physical and is chosen not because it is more important than others but because the constancy has crept into the animal kingdom very slowly and its implications are to some extent traceable. A unicellular organism such as the amoeba exists at a temperature indistinguishable from that of the water in which it lives. Every accident which affects the temperature of the water affects that of the amoeba, the only defence which the creature can put up against a too rigorous environment whether of heat or cold is to flee if it can to more genial surroundings. Within those limits all the processes of its body of digestion of respiration, of movement must take place at the temperature of the water in which the unicellular organism finds itself. Compare the condition of affairs in man the most

the temperature of the body is maintained at a constant level. The constancy of the body temperature is maintained by the balance between the heat gained from the environment and the heat lost to the environment.

The constancy of the body temperature is maintained by the balance between the heat gained from the environment and the heat lost to the environment. The heat gained from the environment is the result of the heat conducted from the environment to the body. The heat lost to the environment is the result of the heat conducted from the body to the environment. The balance between these two processes is maintained by the body's ability to adjust its heat loss to the environment.

The constancy of the body temperature with regard to time is on the other hand something which has been attained at a late stage in the development of the animal kingdom. The so called warm blooded animal in reality the animal whose temperature remains at an even level did not appear until long after the vertebrate level had been reached. Yet this device was developed apparently independently both in birds and mammals.

So manifest are the advantages of a constant temperature that its late development seems almost surprising. The body from one point of view consists of innumerable and ceaseless chemical reactions. The reactions take place at given velocities the velocity of each reaction depending upon the reaction itself and the temperature at which it is taking place. Imagine the whole machine adjusted perfectly to work at 30° C. each reaction progressing at a velocity which (a) is most suitable for its own purpose and (b) fits into the general scheme so nicely that the whole multitude of reactions take place harmoniously. Now alter the temperature from 30° to 10° some of the reactions are affected much by the alteration some little chaos must result and the whole machine be thrown out of gear. Therefore a third condition (c) is necessary namely that the effect of temperature on the velocities of the reactions must be such that when the temperature is altered the reactions alter in speed harmoniously with one another. This fresh condition naturally limits the number and nature of the chemical processes which are available. Some chemical operation might be most desirable and could take place at 37° C. but its insertion into the body would be merely vicious if by refusing to keep pace with its fellows it brought the mechanism to a standstill at 10° C. By maintaining a uniform temperature condition (c) is dispensed with and the body is free to select what chemical reactions are most suitable under the constant condition without reference to the extent to which they may be affected by alteration of the temperature.

The constancy of the body temperature is maintained by a nice adjustment of the heat loss of the body to the heat formation for the mechanism of this adjustment see the article on ANIMAL HEAT here it need only be said that the adjustment is controlled entirely by the nervous system.

**Alkalinity of the Blood.**—The second property of the internal medium, which is maintained at an approximately constant level is the alkalinity of the blood. Great prominence has been given to the study of the hydrogen ion concentration of the blood within the last decade. So far as is known the limits within which the alkalinity of the blood may vary are between pH 8.00 and pH 7.00. The work of L. J. Henderson and of Hasselbalch has gone to show that the hydrogen ion concentration depends not upon the actual quantity of acid or alkali present but upon the balance between the two. In a system consisting of carbonic acid and sodium bicarbonate in solution the hydrogen ion concentration,

$$cH = K \times \frac{(CO_2)}{(NaHCO_3)}$$

where K is a constant and  $(CO_2)$  and  $(NaHCO_3)$  the molecular concentrations respectively of carbonic acid and sodium bicarbonate from which it follows that addition of water to the system will not alter the hydrogen ion concentration.

Every action of the body tends to upset this equilibrium usually in the sense of putting more acid into the blood. muscular exercise for instance adds carbonic and sometimes lactic acid to the circulating medium. How then is the constancy maintained? First by the action of the respiratory system. Increase of the hydrogen ion concentration of the blood leads to increased activity of the respiratory centre and greater consequent loss of carbonic acid by the body in the breath. Secondly the kidney corrects into plasma and if the concentration of acid in the blood falls alkali is secreted in correspondingly excessive amounts in the urine. Whether the central nervous system controls the output of alkali by the kidney is not known. The actual secreting cells of the kidney are not regarded as being operated by nerves if therefore the nervous system plays a part it probably does so by controlling the blood supply.

Two examples have been taken for consideration but the reader can from any book on physiology learn of many more such as the constancy of sugar of protein of the calcium phosphorus ratio of oxygen of haemoglobin and so forth. Yet these are not absolutely constant in the blood but their variation is within small limits—any considerable deflection from which is in health soon redressed.

**The Principle of Maximal Activity.**—The most elementary consideration of the architecture of any structure demands some discussion of the sizes of the various components. This question has received little attention from the physiological point of view. The anatomist has tabulated the average dimensions of the various organs but the physiologist has little to say about the reasons which determine these sizes. What little there is on this subject in the literature of physiology is not always to the point. The human body at rest may be compared to a battleship with her fires lit, her ammunition on board and her guns ready for action. Any description of such a ship is however given in terms of the energy she puts forth, not when at rest but when in the fullest possible activity. She has a speed of so many knots, her hitting power is so and so. Only expressed in those terms the dimensions of her various parts become intelligible. So it is with the body but the difficulties of studying it or any of its parts when the maximum of energy is being developed is very great. Some decision must be come to as to the units in which the energy is to be expressed. In the case of a motor car it is expressed in terms of fuel consumed—so many miles to the gallon or to the litre. In the case of man it may also be expressed in litres—litres of oxygen used in consuming the fuel. A man may use as much as four litres of oxygen per minute. This oxygen is of course used in the tissues themselves and therefore must be carried to them. To carry four litres of oxygen efficiently requires probably about 30 litres of blood therefore 30 litres of blood must pass out of the heart per minute. That fact fixes the size of the aorta and presumably the dimensions of the heart itself. Moreover the blood has to be oxygenated and therefore the dimensions of the lungs are also fixed. Thus the limiting factor in deciding the size of any organ has nothing to do with the events taking place in the resting body but with the maximum activity with which the organ is concerned.

A striking instance is furnished by the splenic vein. Many observers have noted that the splenic vein is large out of proportion to the quantity of blood which usually passes along it. Only recently has it been appreciated that the spleen may hold at a time perhaps one-fifth of the total quantity of blood in the body and that it may contract suddenly expelling possibly  $\frac{1}{2}$  of a litre of blood in a few seconds.

What is true of the body as a whole is true of the individual organs.

The following table gives the quantity of oxygen which they are capable of using in the dog or cat.

Voluntary	Arterial	Arterial	Arterial
muscle	Arterial	Arterial	Arterial
Unaffected	Partial	Partial	Partial
Heart	Arterial	Arterial	Arterial

Thirty years ago physiologists were exercised with the question of the extent to which organs could be cut away without fatal result. Bradford found that the whole of one kidney and the half of the second could be removed in animals without fatal results. It was observed also that the removal of one lung did not appear to be very serious. Men marvelled at the fact that the organs were so unnecessarily large, the standard which they applied was that of rest and not the conditions under which the kidney or the lung was required to function on the greatest scale of which it is capable.

Again it is well known that but a small portion of many of the endocrine organs if left in the body will apparently prevent the obvious sequelae of removal of the whole. Why then should the body contain so much more of the organ than appears necessary and why in many cases will the part left grow perhaps to the original size? Presumably because there are moments when the whole organ is required. It is in relation to such that its size is regulated.

**The Principle of Mobilized Units**—When an organ becomes active it may be conceived of as doing so in one of two ways (of course the two may be combined). The first is that each unit of which the organ is composed may become heightened in activity, the second is that a single unit is capable of only two states, the active and the resting, and that the degree of activity of the organ depends simply on the relative number of active and of resting units which it contains.

For many years the view has been held with regard to the heart that that organ cannot give a partial contraction; if it contracts at all it gives the full contraction of which it is capable in the condition in which it may be at the moment. This was known as the 'all or none' principle. It seemed to indicate that not only did each fibre of the heart muscle contract to its full extent but that when contraction took place all the fibres in the heart contracted. These are two separate points. For the moment the applicability of the all or none principle to the cell will be considered. More recently the principle has been applied both to striated muscle and to nerve. As now conceived each fibre of which a skeletal muscle is composed contracts to its full extent if it contracts at all but unlike the heart not all the fibres need necessarily contract. Thus the degree of shortening of the muscle will depend upon the number of fibres which are thrown into contraction and not upon the degree of contraction of each.

Very beautiful records have recently been obtained of the impulses which pass up sensory nerve fibres; the same principle holds good. There is a standard impulse which can pass up that is a property of the nerve. The gradation of the sensation depends upon the number of such which pass along the nerve in a given time and on the number of nerve fibres which are stimulated simultaneously.

With regard to the applicability of the 'all or none' law to secreting cells there is nothing known.

Passing from the consideration of cells to that of organs one finds that there is frequently a unit between the cell and the organ, the lung consists of alveoli, the same is true of the salivary gland, the kidney consists of tubules, and so forth. Till recently it was assumed that in any one organ all the units are

at the time the activity of each unit being graded in accordance with its position. With regard to the kidney, Raper and Wain have shown that otherwise the degree of activity of the organ is graded in accordance with the number of alveoli which are active. This is true for the tubules appear to be active in the kidney. This would reason for supposing the 'all or none' principle to be applicable to the units of the lung. In normal conditions the whole of a portion of the lung is being involved when the respiration is more laboured a larger portion of the lung becomes involved. The application of the 'all or none' principle to the units of the lung is however on a less scale than in the case of the kidney. In the latter case the portions have been seen to go in and out of action the blood flow through them being at times suspended in the lung in a matter of inference.

The most striking instance of the mobilization of units is that of the capillaries as observed by Krogh. In a muscle for instance the capillaries run parallel to the muscle fibres. When the muscle is at rest the majority of the capillaries are entirely closed no blood whatever running along them. As the muscle becomes more and more active a correspondingly greater number of capillaries open and the maximum may be many times the number at rest.

**Principle of Substantial Reserves**—The principal materials (grains) which the body requires are carbohydrate, fat, protein, water and oxygen. In the case of each the body carries some sort of store beyond that placed at the immediate seat of metabolism.

**Carbohydrate**—The blood contains about 1 gram of sugar that is a little more than half an hour's supply for the whole body. The remaining carbohydrate is stored as glycogen. Of this about half is distributed throughout the tissues generally and may therefore be regarded more or less as being at the seat of its metabolism. The remaining half amounting to 15 grams or half a day's supply is to be found in the liver which acts as a store for the body as a whole. Thus the body has a store of about one half day's supply of carbohydrate—250–300 grams being the figure put down in the standard dietaries for daily consumption. That is not to say that after 12 hours abstinence there is no carbohydrate left in the body but it means that the organism is gradually falling back on something else.

Fat is stored on a much greater scale than carbohydrate. The amount of fat stored in the body naturally differs in different individuals within very wide limits but it has been established as the result of numerous experiments that a portion of the fat laid down in the body is directly derived from what is eaten. Thus if some oil of low melting point be taken in the food it may at once be recognised as entering into the store of fat reserved in the body.

Whilst it is quite clear that carbohydrate eaten may be stored as carbohydrate and used as such and while it is equally clear that fat eaten may be stored as fat the more arresting question arises—Is not much of the fat of the body essentially a store of carbohydrate? In order to establish this thesis it would be necessary to prove (1) that carbohydrate taken may be laid on as fat and (2) that when carbohydrate is needed fat may be reconverted into carbohydrate or at all events used as carbohydrate is used. That carbohydrate taken in the food may be laid on as fat was proved by the classical experiment of Lawes and Gilbert. In this two young pigs were chosen from the same litter and while one was killed and analysed the other was 'fed on grains' a diet which is practically free from fat consisting of protein and carbohydrate. The amount of fat put on by the growing pig was greater than could be accounted for on the assumption that it was formed from protein. Indeed since the days of Lawes and Gilbert it has become increasingly doubtful whether fat can be formed from protein on any considerable scale in the mammal.

To pass to the possible reconversion of fat into carbohydrate—that is at the moment a subject on which the highest authorities are in controversy. It may be that when muscle is in want of carbohydrate and cannot get any from the usual sources fat is reconverted, but it may not be so. If it is not, however, there appears to be but one possibility namely, that the muscle can

the air is taken into the lungs through the capillaries. It is here that the oxygen is taken up by the haemoglobin of the red blood cells. The oxygen is then transported to the tissues where it is used for the oxidation of food.

**Oxygen**—Oxygen is stored in the body in the form of haemoglobin in the red blood cells. It is also stored in the form of myoglobin in the muscle. The oxygen is taken up by the haemoglobin of the red blood cells. The oxygen is then transported to the tissues where it is used for the oxidation of food. The oxygen is taken up by the haemoglobin of the red blood cells. The oxygen is then transported to the tissues where it is used for the oxidation of food. The oxygen is taken up by the haemoglobin of the red blood cells. The oxygen is then transported to the tissues where it is used for the oxidation of food.

**The Principle of Specific Chemical Response**—There are a number of relatively simple chemical substances any of which if injected into the body cause the body to produce some other substance which unites with and in a sense neutralises it. To give three examples—If a fatty acid be administered to the alimentary canal the acid will be absorbed by the villi the cells of which will produce glycerine and the result will be a neutral fat. If on the other hand benzoic acid be administered it will get so far as the kidney and there the kidney cells will produce glycine turning it into hippuric acid. Lactic acid similarly if thrust into the general circulation will be excreted as ammonium lactate the ammonia being produced not by the cells of the body generally but by those or certain of those in the kidney. We have now arrived at the confines of the great subject of immunity—and perhaps outside the region of the present article.

**The Principle of Dual Control**—The body has two ways of doing a great many things. Examples of this principle are so numerous as to be found in almost any system of the body. To take the point at which two of the most important systems of the body—the nervous and the respiratory systems—touch let us consider the nervous control of respiration.

The essence of respiration is a rhythmic outflow of alternate inspiratory and expiratory impulses from the brain to the muscles concerned. That rhythm is probably but not certainly inherent in the brain itself but it is regulated by influences which play upon the brain. These influences fall into two general categories—those which arrive along the nervous paths from the lungs and elsewhere and those which are borne to the brain in the blood stream.

An increase of total respiration may then take place in either of two ways—(a) many forms of irritation in the lung produce an increased total ventilation which is abolished by cutting the vagi and which may therefore be regarded as being due to special stimuli passing up along these nerves. (b) increase of carbonic acid in the blood even in the absence of nervous stimulation will so act upon the respiratory centre as to increase the total ventilation. During muscular exercise both the nervous and the chemical factors come into play the nervous is the first to be initiated and therefore it may be regarded as the most sensitive but even were it not involved a sufficient regulation could probably be carried out by the carbonic acid in the blood.

The respiratory centre furnishes another example. This time

it is a combination of a nervous with a physical regulation. The principles are principally based on the observations of Professor Richet. If a dog lies down in the sun he will very shortly commence to pant in rapid shallow respirations passing air over his tongue and through his respiratory passages. According to Professor Richet this tachypnoea is associated with an actual lowering of the body temperature and is due to stimuli from the warm air reaching the respiratory centre via the sensory nerves. But even did not this nervous regulation of the body temperature take place another would supervene of perhaps a cruder character for as soon as the body temperature began to rise the warmer blood reaching the respiratory centre would itself produce an increased ventilation. Here again the nervous effect is the first to be invoked and presumably the more delicate.

The digestive system abounds with examples of duality. Of the three principal forms of food which are digested—carbohydrates, proteins and fats—the organs for the secretion of the digestive ferments are in all cases reduplicated. Starch is turned into sugar both by the saliva and by the pancreas. Protein is broken down to the peptone stage both by the pepsin of the stomach and the trypsin of the pancreas while to quote Leathes, two fat-splitting enzymes are present in the intestinal contents, one being provided by the pancreatic juice and the other by the intestinal juice. The action of the intestinal juice is however overshadowed by that of the pancreatic juice.

Not only are the ferments which effect digestion duplicated but there is a measure of duplication about the mechanisms responsible for their secretion. The processes of the alimentary canal are actuated some by nervous stimuli some by chemical but in large measure by both. The secretion of saliva is entirely actuated by nervous stimuli, gastric juice is secreted largely as a result of nervous stimuli but its flow is maintained by chemical bodies. In the secretion of pancreatic juice chemical stimuli play the more prominent part, nervous stimuli not however being entirely absent whilst the secretion of the intestine is—so far as is known—due entirely to hormones. If the whole process from end to end be reviewed some of the statements made about the respiratory centre are applicable. The process of digestion is initiated by nervous and maintained by chemical stimuli. As Dr Anrep has pointed out the further the food gets from the surface of the body the less is it under the influence of the nervous the more is it under the influence of the hormonal system.

The vascular system no less than the alimentary is subject to both hormones and to nervous stimuli inasmuch as nearly all its parts are innervated by the sympathetic system (for adrenaline acts on the nerve endings of that system). Thus Florey has shown in the intestine of the dog that a sudden sound will cause the mucous membrane to pale in a matter of a few seconds. If the nerves to this piece of intestine be severed the noise will still cause the intestine to pale but after a much longer time—in about a quarter of a minute. The paling is in each case due to constriction of the small vessels. In the first case the constriction is initiated by nervous stimuli reaching the mucosa along the branches of the splanchnic supply in the second the blanching is due presumably to adrenaline secretion. The case is not however entirely parallel to that of the nervous and chemical government of the pancreas inasmuch as the adrenaline secretion is itself due to nervous stimulation so that the reduplication is merely a reduplication of the paths by which the nervous system can control the calibre of the vessels.

What applies to the blood vessels applies so far as the relative roles of the nervous and the endocrine systems are concerned to many other structures in the body which will at once occur to the reader. Many organs have not only a chemical and a nervous mechanism but also a double nervous supply. That however will be treated later in this article under *Antagonistic Nerves*.

Two organs in the mammals stand out as having no substitutes—the lungs and the generative organs and in each case the fact is a little interesting because lower down in the animal kingdom that simplicity does not exist. Apart from the existence of gills in the frog there is a cutaneous respiration so that it, even

in air has two alternative. As regard reproduction of course the most primitive form is simply by division. Reproduction by fission exists in many forms of life cellular and asexual reproduction but in all the higher type of the animal kingdom has been given up.

**The Principle of Antagonistic Nerves**—There are numerous places in the body in which the actual condition of the organ at any moment is obtained by the balancing of antagonistic influences upon it. Four examples may be given.

(1) The rate of the heart beat is regulated by two nerves one of which the vagus when stimulated makes the heart slow while the other the sympathetic drives it faster. Normally its pace is neither so fast nor so slow as that of which it is capable a fact to be accounted for by the balance of influences passing down the two nerves. If this balance alters the rate changes. (2) The diameter of the pupil of the eye is under the control of two nerves one of which if stimulated dilates the pupil while the other constricts it. The actual size depends upon the relative influence of the two at any one moment. (3) The movements of the joints (say of the thigh joint) in walking are obtained by the balancing of the muscles which move the joint. It is not merely that alternately one set of muscles comes into action whilst the antagonistic set goes out of action but each set is the whole time in a greater or less degree of tone. The whole action of the thigh depends upon the relative degree of the various muscles which exert an antagonistic action. (4) In the highest animals delicate manual movements have been secured by the antagonism of the thumb to the fingers especially to the first finger.

The four examples cited if examined show little similarity in the mechanism by which the antagonism is produced. In the first the nerves act presumably in the same structure in the heart tissue. In the pupil the two sets of nerves act on different muscles. These do not pull directly against one another like men in a tug of war the muscle which tends to close the pupil is a ring that which tends to open it is radial. In the thigh you have definite groups of muscles pitted against one another and pulling the bone in opposite directions while in the finger and thumb there are actually different organs.

Thirty years ago thought was focussed on antagonistic nerves because they were supposed to initiate opposite phases of protoplasmic activity in the organs which they supplied. All living matter was conceived as capable of anabolism (building up) and katabolism (breaking down) the slowing of the heart due to vagus stimulation was supposedly the expression of accentuated anabolic activity the quickening of the heart due to sympathetic stimulation was held to indicate increased katabolism. Of the known cases of antagonistic nerves there are so few in which the two sets of fibres end in the same tissue that their connection with anabolic and katabolic activity has passed out of the picture.

It seems likely that their principal interest lies in the fact that by use of such antagonisms nature has built up a body capable of potentialities which it (the body) would not otherwise possess. By the balancing of the finger against the thumb more accurate and more delicate movements can be made than those of which either finger or thumb separately is capable. By the balancing of the thigh muscles against one another an accuracy of poise is secured which would not otherwise exist. The same is clearly true of the pupil and had we the necessary discernment we could probably see the application of the general principle involved to the heart and blood vessels.

**The Principle of Integrative Adaptation**—When the body is subjected to such adverse conditions that constancy of the composition of the blood cannot be maintained the lack or excess of some one constituent may be of considerable gravity. In such circumstances some form of adaptation frequently takes place. This adaptation consists in an alteration in quite a number of factors each of which changes only a little though when the whole series of changes are integrated the net result is a very large degree of adaptation to the new environment. In such cases the body is not restored to its original degree of efficiency, but it has moved a considerable distance in that direction.

Examples may be drawn from the response of the body to

exercise at high altitudes to anaemia and so forth for which the article on ANOXAEMIA MUSCULAR EXERCISE VASCULAR SYSTEM and ANAEMIA may be consulted. (J. BAR.)

**PIACENZA** (Lat. *Placentia*) a town and episcopal see in Emilia Italy, the capital of the province of Piacenza 41 m S.E. of Milan and 91 m N.W. of Bologna by rail. Pop. (1931) 46,100 (town) 65,500 (commune). It lies on the Lombard plain 17 ft above sea level near the Po which here is crossed by road and railway bridge each about 600 yd long just below the confluence of the Trebia. It is still surrounded by walls with bastions and fosse in a circuit of 4 miles. The cathedral was erected between 1112 and 1133 in the Lombard Romanesque style. The campanile is 51 ft high. The entire edifice has been restored since 1898 and the frescoes by Guercino, Lodovico Carracci and Procaccio seem inappropriate to its severe style. In Sant'Antonino the deputies of the Lombard League swore to the conditions of peace ratified in 1183 at Constance. San Francesco is a Gothic edifice begun by the Franciscans in 1178. S. Savino a Romanesque building of A.D. 903 (rebuilt in 1107 and restored in 1903) contains a mosaic pavement with curious representations including one of a game of chess. S. Sisto (1499) once contained Raphael's Sistine Madonna now in Dresden sold in 1754 to Frederick Augustus III. Its place is occupied by a copy by Avanzini and there are also several good intarsias by Bartolomeo da Busseto. Of the secular buildings the most interesting is the Palazzo Comunale begun in 181 built in marble and brick with beautiful windows one of the finest buildings of its kind in Italy. The Palazzo dei Tribunali and the Palazzo degli Scotti are early Renaissance brick buildings with terra cotta decorations. The huge Farnese palace was begun after Vignola's designs by Margaret of Austria in 1558 but it was never completed and since 1800 it has been used as barracks. The town has a motor car factory. It is an important agricultural centre. Petroleum wells have been bored hereabouts.

Piacenza was made a Roman colony in 18 B.C. in which year it afforded protection to the remains of the Roman army after the battle of the Trebia (q.v.). In 205 it withstood a siege by Hasdrubal. Five years later the Gauls burned it and in 190 it was recruited with 3,000 families. In 187 it was connected with Ariminum and the south by the construction of the Via Aemilia. Later on it became a very important road centre the continuation northwards of the Via Aemilia towards Milan with a branch to Ticinum crossed the Po there and the Via Postumia from Cremona to Dertona and Genoa passed through it. Later still Augustus reconstructed the road from Dertona to Vada and into Gallia Narbonensis and gave it the name of Julia Augusta from Placentia onwards. The rectangular arrangement of the streets in the centre of the town through which passes the Via Aemilia is a survival from Roman times. Placentia is mentioned frequently as an important military point in Roman times. It was one of the leading members of the Lombard League. In 1447 the city was captured and sacked by Francesco Sforza. Having been occupied by the papal forces in 1512 it was in 1545 united with Parma (q.v.) to form an hereditary duchy for Pierluigi Farnese nephew of Paul III. In 1796 it was occupied by the French. In 1848 Piacenza was the first town of Lombardy to join Piedmont but was reoccupied by the Austrians till 1859.

**PIANOFORTE** The group of keyed stringed musical instruments, among which the pianoforte is latest in order of time has been invented and step by step developed with the modern art of music. During the 10th century the 'organum' arose, an elemen-

us that even then clavichords were made longer in ratio by repetition of the same order of key. The introduction of the chromatic order led to tributes to the success of the instrument and the consequent endeavour to restore the three natural notes of the Greeks—the diatonic, chromatic and enharmonic. But this named was not attained until equal temperament fully developed by J. S. Bach. Viridung gives a view of the clavichordum

FIG 3—VIRIDUNG'S CLAVICHORDIUM (1511) FACSIMILE WOODCUT REVERSED TO CORRECT THE KEYBOARD

chordum the virginal the clavichimbalum and the clavicytherium. We reproduce three of them (figs 3, 6 and 8) omitting the virginal as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed which puts the keyboards entirely wrong and that in Luscinius's Latin translation of Viridung (*Viridung sive praxis musicae* Strasbourg 1536) which has been hitherto chiefly followed two of the engravings, the clavichimbalum and the clavicytherium are transposed another cause of error.

Still commonly known as monochord Viridung's clavichord was really a box of monochords, all the strings being of the same length. We observe in this drawing (fig 3) the short soundboard which always remained a peculiarity of the clavichord and the straight soundboard bridge—necessarily so when all the strings were of one length. To gain an angle of incidence for the tangents against the strings the keys were splayed, an expedient further rendered necessary by the fretting—three tangents being placed to give three different notes from each single group of strings tuned in unison. In the drawing the strings are merely indicated. The German for fret is *Bund* and such a clavichord in that language is known as a gebundenes Clavichord, both fret (to

FIG 4—MANICORDO (CLAVICHORD) D. ELEONORA DI MONTALVO (1659) KRAHM MUSEUM FLORENCE

rub) and *Bund* (from *binden* to bind) having been taken over from the lute or viol. The French and Italians employ *touche* and *tasto* (touch). Praetorius who wrote a hundred years later than Viridung says two, three and four tangents were thus employed in stopping.

Clavichords were made with double fretting up to about the year 1700—that is to say to the epoch of J. S. Bach who taking advantage of its abolition and the consequent use of independent pairs of strings for each note was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach

the clavichord was made longer in ratio by repetition of the same order of key. The introduction of the chromatic order led to tributes to the success of the instrument and the consequent endeavour to restore the three natural notes of the Greeks—the diatonic, chromatic and enharmonic. But this named was not attained until equal temperament fully developed by J. S. Bach. Viridung gives a view of the clavichordum

FIG 5—CLAVICHORD TANGENT. The position when the key is depressed the tangent is brought into contact with the string from the depth of the key. The back string is kept from vibrating by means of the last string. The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name and can hardly have been of German origin but it remained longest in use in Germany—until even the beginning of the 19th century.

The next instrument described by Viridung is the virginal (*virginalis* proper for a girl) a parallelogram in shape having the same projecting keyboard and compass of keys as the clavichordum. Here we trace derivation from the psalter in that the soundboard covers the entire inner surface of the instrument.

The next instrument described by Viridung is the virginal (*virginalis* proper for a girl) a parallelogram in shape having the same projecting keyboard and compass of keys as the clavichordum. and the disposition of the strings is triangular. The virginal in Viridung's drawing has an impossible position with reference to the keyboard which renders its reproduction as an illustration useless. But in the next drawing, the clavichimbalum this is rectified and the drawing reversed on account of the keyboard can be accepted as roughly representing the instrument so called (fig 6). There would be no difference between the clavichimbalum and the virginal were it not for a peculiarity of keyboard compass which emphatically refers itself to the Italian "spinetta" a name

united by Viridung or by his countryman Arnold Schlick who in 1511 published his *Spiegel der Orgelmacher* (Organ builder's Mirror) and named the clavichordium and clavimbala as instruments. In the first place the key-board began appearing with B natural instead of F makes the clavichordium male than the virginal he brings in this manner the compass of the next place it is almost certain that the clavichord compass began apparently upon a semitone interval with a short measure or short octave organ compass a very old keyboard arrangement by which the first three notes while appearing to be B, C and C sharp were tuned to G, C and A. The origin of this may be deduced from the psalter and many representations of the regal and its object appears to have been to obtain dominant bases for cadences harmonious closes having early been sought for as giving pleasure to the ear.

Authority for this practice is to be found in Mersenne who in 1636 expressly describes it as occurring in his own spinet (*espinette*). We read (*Harmonie Universelle* Paris 1636 liv. 3 p. 101) — Its longest string is little more than a foot in length between the two bridges. It has only thirty one keys [*marches*] in a keyboard and as many strings over its sound board so that there are five keys hidden [he now refers to the illustration] on account of the perspective—that is to say three diatonic and two chromatic of which the first is cut into two but these sharps serve to go down to the third and fourth below the first step C sol [tenor clef C] in order to go as far as the third octave for the eighteen principal steps make but an eighteenth that is to say a fourth more than two octaves. Mersenne's statement sufficiently proves first the use in spinets as well as in organs of what we now call short measure and secondly the object of divided sharps at the lower end of the keyboard to gain lower notes.

As regards the kind of plectra earliest used we have no evidence. The little crow quill points project from centred tongues in uprights of wood known as jacks (fig. 7) which also carry the dampers and rising by the depression of the keys in front the quills set the strings vibrating as they pluck them in passing. J. C. Scaliger in *Poetices libri septem* (1561 p. 51 c. 1) states that the clavichordium and harpichordum of his boyhood were called spinets on account of those quill points (*ab illis mucronibus*) and attributes the introduction of the name spinetta to them from *spina* a thorn the meaning being extended to any small pointed object such as a quill. We will leave harpichordum for the present but the early identity of clavichordium and spinetta is certainly proved. Scaliger's etymology remained unquestioned until Signor Ponsicchi of Florence discovered another but less acceptable derivation. He found in a rare book entitled *Conclusione nel suono dell'organo di D. Adriano Banchieri* (Bologna 1608) the following passage which translated reads: Spinetta was thus named from the inventor of that oblong form who was one Maestro Giovanni Spinetti a Venetian and I have seen one of those instruments in the possession of Francesco Stivori organist of the magnificent community of Montagnana within which was this inscription—*Joannes Spinetus Venetus fecit A.D. 1503*. Scaliger's and Banchieri's statements may be combined as there is no discrepancy of dates or we may rely upon whichever seems to us to have the greater authority always bearing in mind that neither invalidates the other. In France the word *epinette* still stands for both spinet and chicken-house which seems to strengthen the first named theory. A spinet dated 1490 was shown at Bologna in 1888 another old spinet in the Conservatoire Paris is a pentagonal instrument made by Francesco di Portolupis at Verona 1523. The Milanese Rossi were famous spinet makers and have been accredited (*La Nobiltà di Milano*, 1595) with the recessing of the

FIG. 7.—SPINET JACK. Showing the quill which twangs the string as it upwardly rises but being hinged it slides quietly past on its return.

keyboard which had previously entirely projected by this recessing a greater width was obtained for the sound board. The spinets by Annibale Rosso at South Kensington dated respectively 1555 and 1577 show this alteration and may be compared with the older and purer form of one dated 1568 by Marco Jadra (also known as Marco dalle spinette or dai cembali). The apparent compass of the keyboard in Italy generally exceeded four octaves by a semitone E to F but we may regard the lowest natural key as usually C and the lowest sharp key as usually D in these instruments according to short measure.

FIG. 8.—VIRIDUNG'S CLAVICHYTERIUM (UPRIGHT HARPSICORD) 1511 REVERSED FACSIMILE WOOD CUT.

equivalent to the contemporary Italian *clavicordo* and Flemish *clavysingel*. From the latter we arrive at the French *clavecin* the spinet being simply a *petit clavecin*.

Mersenne (*op. cit.* liv. iii p. 138) gives three sizes for spinets—one  $\frac{1}{2}$  ft wide tuned to the octave of the *ton de chapelle* (a half tone above the present English medium pitch) one of  $3\frac{1}{4}$  ft tuned to the fourth below and one of 5 ft tuned to the octave below the first the last being therefore tuned in unison to the chapel pitch. The octave spinet of trapeze form was known in Italy as *ottavina* or *spinetta di serenata*. It had a less compass of keys than the larger instrument being apparently three and two third octaves E to C—which by the short measure would be four octaves C to C. These little spinets were placed upon the larger ones in performance and used to heighten the

FIG. 9.—CRISTOFORI'S ESCAPEMENT ACTION (1720). The hinged lever when struck by the jack transmits the blow to the butt thus having the effect of the winged hammer to withdraw the strings.

brilliant effect. In the double rectangular clavysingel of the Netherlands in which there was a movable octave instrument we recognize a similar intention. There is a fine spinet of this kind at Nuremberg. Praetorius illustrates the Italian spinet by a form known as the *spinetta traversa*—an approach towards the harpichord the tuning pins being immediately over the keyboard. This transposed spinet more powerful than the old trapeze one became fashionable in England after the Restoration when Haward Keene, Slade Player Baudin the Hitchcocks Mahoon and by the Harrn family and others made such spinets during a period for which we have dates from 1664 to 1784. Pepys

bought his Espine e from Charles H. and for a J. 1664 Thomas Hitchcock (for whom he wrote the 164 and 1703 written on keys and jacks of some 1611-1612) name and having divided the harp into two parts, the construction spirets giving them the wide compass of the octave from G to G with very fine ke board in which the harp is inlaid with a slip of the ivory or ebony as the case might be of the natural.

We have now to ask what was the difference between Scarrers harpichorium and his clavicymbal. Galilei the father of the astronomer of that name (*Disegno della musica antica e moderna* Florence 1581) says that the harpichord was so named from having resembled an arpa giacente a prostrate or couched harp proving that the clavicymbal was at first the trapeze shaped spinet and we should therefore differentiate harpichord and clavicymbal as derived from the harp and psalter respectively.

The Latin name clavicymbalum having early been replaced by spinet and virginal was in Italy and France bestowed upon the long harpichord and was continued as clavicebalo and clavecin. Much later after the restoration of the Stuarts harpichord was accepted and naturalized in England as harpsichord which we will define as the long instrument with quills shaped like a modern grand piano. We can point out no long instrument of this kind so old as the Roman cembalo at South Kensington. The outer case is of finely tooled leather. It has a compass of nearly four octaves E to D and the natural keys are of boxwood.

The startling piano e forte of 1598 brought to light from the records of the house of D'Este by Count Valdrighi of Modena (see Van der Straeten vi 1) we are disposed to regard not as an anticipation of Cristofori's subsequent invention of the pianoforte but as an ordinary cembalo with power to shift by a stop from two unisons (forte) to one string (piano) at that time a Flemish practice and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition.

About the year 1600 when accompaniment was invented for monody large cembalos were made for the orchestras to bring out the bass part the performer standing to play. Such an instrument was called archicembalo a name also applied to a large cembalo made by Vito Trasuntino a Venetian in 1606 intended by thirty one keys in each of its four octaves to restore the three genera of the ancient Greeks.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century. We find them imported into England. The following citations quoted by Rimbault in his *History of the Pianoforte* are from the privy purse expenses of King Henry VIII.

1530 (April) Item the vii daye paid to William Lewes for a payer of virginals in one coffer with iii stoppes brought to Greenwich in li. And for a payer of virginals in one coffer brought to the More other iii li.

Now the second instrument may be explained (virginals meaning any quilled instrument) as a double spinet like that at Nuremberg by Martin van der Beest the octave division being movable. But the first cannot be so explained the four stops can only belong to a harpsichord and the two pair instrument to a double manual. Again from the inventory after the king's death (see Brit Mus Harl MS 1419) fol 247—

Two fair pair of new long Virginals made harp fashion of Cipres with keys of ivory having the King's Arms crowned and supported by his Grace's beasts within a garter gilt standing over the keys.

This is probably another double keyboard harpsichord. We read

FIG 10—CRISTOFORI'S PIANO E FORTE (1726) KRAUS MUSEUM FLORENCE

in the inventory of the furniture of Warwick Castle 1534 a faire pair of new virginals and in the Henrye inventory 1635 a great pair of new virginals. Hans Ruckert the great maker of the 17th century who had invented the harpichord and the clavicymbal and the harpichord from the organ and the harp and the clavicymbal which began his work in the late 16th century. Joseph Kirckmann in 1798 received a number of letters from London constructed except in Italy without the clavicymbal which was known throughout the 17th century with no upper and for lower keyboard with the clavicymbal and on Jan Ruckert's death Jan Cuche about 1740. Before that time the double keyboard in Flemish harpichords were really a transposing expedient to change the pitch a fourth from natural to authentic and never a wide range the same groups of keys.

After the Anwerp make declined London became pre-eminent for harpichords—the representative makers being Jacob Kirckmann and Burkhard Tschudi pupils of a Flemish master one Tabel who had settled in London and whose business Kirckmann continued through a marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time by which Handel became Handel and Schmidt Smith Kirckmann dropped his final n and Tschudi became Shudi but he retained the full spelling in the titles of the splendid harpsichords he made in 1666 for Frederick the Great which are still preserved at Potsdam. By the great makers the harpsichord became a larger heavier strung and more powerful instrument and fancy stops were added to vary the tone effects. To the three shifting registers of jacks were added the lute the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge and the harp a muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used the left hand one a combination of a unison and lute.

The right hand pedal was to raise a hinged portion of the top or cover and thus gain some power of swell or crescendo an invention of Roger Plenius to whom also the harp stop may be rightly attributed. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (Haward) as early as 1666 as we learn from *Miles Musick's Monument* p 235. The French makers preferred a kind of knee pedal arrangement known as the genouillere and sometimes a more complete muting by one long strip of buff leather the sordine. As an improvement upon Plenius's clumsy swell Shudi in 1669 patented the Venetian swell a framing of louvers like a Venetian blind which opened by the movement of the pedal and becoming in England a favourite addition to harpsichords was early transferred to the organ replacing the rude nag's head swell.

To keep his collection of musical instruments in playing order Prince Ferdinand dei Medici engaged a Paduan harpsichord maker Bartolommeo Cristofori the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well known writer the Marchese Scipione Maffei his description appeared in the *Giornale dei letterati d'Italia* a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it with a technically imperfect translation in his *History of the Pianoforte*. We learn from it that in 1709 Cristofori had completed four gravecembali col piano e forte—keyed psalteries with soft and loud—three of them being of the long or usual harpsichord form. The sketch of his action in Maffei's essay shows an incomplete stage in the invention although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper working when the key is depressed by the touch in a small projection from the centred hammer butt. The return governed by a spring must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover the hammer had each time to be raised the entire distance of its fall. There are however two pianofortes by Cristofori dated respectively 1700 and

appearance of being reduced to a simple action differing very much from the original.

Burney tells us that the first square piano would not be so good as the original, however that he says he saw a copy of it made by Zupercar. It is not clear from the near approach of the hammer to the key, but he notes that Schroeder's piano is better at once. This defect is remedied by the German action.

Another piano action had, however, come into use some time or even earlier in Germany. The diagram shows the

FIG 15—EARLIEST KNOWN PIANO ACTION ON THE GERMAN PRINCIPLE OF ESCAPEMENT WHEREBY THE PIVOT RISES WITH THE KEY AND THROWS THE BUTT AGAINST A FIRM RESISTANCE

simplest form is to be attributed to V. C. Mahillon who found it in a square piano belonging to Henri Gosse, painter of Brussels (fig. 19). The principle of this action is that which was later perfected by the addition of a good escapement by Stein of Augsburg and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and permit of its transformation into a square piano. It will be observed that the hammer is, as compared with other actions, reversed and its pivot rises with the key necessitating a fixed rail against which the hammer butt strikes. It was Stein's merit to graft the hopper principle upon this simple action and Mozart's approbation of the invention when he met with it at Augsburg in 1777 is expressed in a well-known letter addressed to his mother. No more blocking of the hammer destroying all vibration was henceforth to vex his mind. He had found the instrument that for the rest of his short life replaced the harpsichord. V. C. Mahillon secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg dated 1780 and has Stein's escapement action (fig. 16) two unisons and the knee pedal.

Mozart's own grand piano preserved at Salzburg and the two grand pianos (the latest dated 1790) by Huhn of Berlin preserved

FIG 16—STEIN'S ACTION AFTERWARDS CALLED VIENNESE (1780). The pivot of the hammer rises with the key and the blow is caused by the end of the hammer coming into contact with the escapement.

at Berlin and Charlottenburg follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as *ceste*, which no doubt Stein had also. The wrest plank is not inverted nor is there any imitation of Cristofori. Stein's instrument was accepted as a model in Berlin as well as Vienna to which city his business was transferred in 1794 by his daughter Nanette known as an accomplished pianist and friend of Beethoven who at that time used Stein's pianos. Streicher a pianist, who married Nanette, further improved the

FIG 17—GERMAN SQUARE ACTION (1780). THE ESCAPEMENT IS EFFECTED AT THE POINT WHERE THE HOPPER FALLS INTO THE NOTCH. PIANO BY WAGNER DRESDEN.

was referred to the Harpsichord which after its introduction into England. He told us without giving the exact date that the first hammer harpsichord that came to England was made by an English lute maker at Rome a Father Wood for an English gentleman Samuel Crisp of Chelmsford. The tone of this instrument was superior to that produced by quill with the advantage of piano and forte expression so that although the touch and mechanism were imperfect yet in a slow movement like the 'Dead March' in *Saul* it excited wonder and delight. Fulke Greville the third bought this instrument for 100 guineas and it remained unique in England for several years until Plenus the inventor of the lutechord made a piano forte in imitation of it. In this instrument the touch was better but the tone was inferior. Plenus produced his lutechord a *sostenente* harpsichord in 1745 and Mason imported a piano forte ten years later. Burney further tells us that the arrival in London of J. C. Bach in 1769 was the motive for several of the second-rate harpsichord makers trying to make pianoforte but with no particular success. Of these Americus Backers (d. 1776) said to be a Dutchman appears to have gained the first place. He was afterwards the inventor of the so-called English action based upon Cristofori's and may have made the instrument referred to in an old play bill of Covent Garden in Messrs. Broadwoods' possession dated May 16 1767 which has the following announcement—

End of Act 1. Miss Brickler will sing a favourite song from *Judith* accompanied by Mr. Dibdin on a new instrument called Piano Forte.

Backers's 'Original Forte Piano' was played at the Thatched House in St. James's Street London in 1773. Ponsicchi has found a Backers grand piano at Pistoria dated that year.

The escapement lever is suggested by Cristofori's first action to which Backers added a contrivance for regulating it by means of a button and screw (see fig. 18). The check is from Cristofori's second action. John Broadwood and Robert Stodart were friends Stodart having been Broadwood's pupil and they were the assistants of Backers in the installation of his invention. On his deathbed he commended it to Broadwood's care but Stodart appears to have been the first to advance it—Broadwood being probably held back by his partnership with his brother in law the son of Shudi in the harpsichord business. (The elder Shudi had died in 1773.) Stodart soon made a considerable reputation with his grand pianofortes a designation he was the first to give them. In Stodart's grand piano we first find an adaptation from the lutechord of Plenus of steel arches between the wrest plank and belly-rail bridging the gap up which the hammers rise. These are not found in any contemporary German instruments but may have been part of Backers's. Zumpe's small square piano had met with great success, he was soon enabled to retire, and his imitators, who were legion, continued his model with its hand stops for the dampers and sourdine, with little change but that

which rendered the key return the direct result of the hammer from the check.

John Broadwood took the direct action from the hand to improve it and in 1781 he succeeded in entirely reconstructing it. He raised the key plank and put from the right hand side as in the clavier of the back of the case and

FIG 18—GRAND PIANO ACTION (1776) THE ENGLISH ACTION OF AMERICUS BACKERS

improvement universally adopted after his patent No 1,579 of 1783 expired. In this patent we first find the soft and sustaining pedals since universally accepted but at first in grand pianofortes only. John Geib patented (No 1,571 of 1786) the hopper with two separate escapements one of which was soon adopted in the grasshopper of the square piano it is believed by Geib himself

FIG 19—BROADWOOD'S GRAND PIANO ACTION (1884) ENGLISH DIRECT MECHANISM

The hopper is thrown from the notch in the butt by the slanting blow given by the set-off button when the hopper rises

and Petzold a Paris maker appears to have taken later to the escapement effected upon the key

To return to John Broadwood—having launched his reconstructed square piano he next turned his attention to the grand piano to continue the improvement of it from the point where Backers had left it. He called in the aid of professed men of science—Tiberius Cavallo who in 1788 published his calculations of the tension and Dr Gray of the British Museum. The problem

was solved by dividing the sound board bridge the lower half of which was advanced to carry the bass strings which were still of brass. Even the first attempts to equalize the tension and improve the striking place were successful in improving the tone greatly. To please Dussek Broadwood in 1791 carried his five octave F to F keyboard by adding keys upwards to five and a half octave F to C. In 1794 the additional bass half octave to C which Shudi had first introduced in his double harpsichords was given to the piano.

The first square piano made in France is said to have been constructed in 1766 by Sebastian Erard a young Alsatian. In 1786 he came to England and founded the London manufactory of harp and pianofortes bearing his name. Erard took out his first patent for a repetition action in 1808. He did not however succeed in producing his famous repetition or double escapement action until 1811 it was then patented by his nephew Pierre Er

FIG 20—COLLARD'S GRAND PIANO ACTION (1884) ENGLISH ACTION WITH REVERSED HOPPER AND CONTRIVANCE FOR REPETITION ADDED OPERATING UNDER THE BUTT

ard. When the patent expired in England in 1835 it had proved a loss from the difficulties of carrying out the invention. This induced the House of Lords to grant an extension of the patent.

Erard invented in 1801 an upward bearing to the wrest plank bridge by means of agraffes or studs of metal through holes in which the strings are made to pass bearing against the upper side. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure bar bearing of later introduction is claimed for the French maker Bord.

The first to see the importance of iron combined with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession John Isaac Hawkins known as the inventor of the ever pointed pencil. He was living at Philadelphia USA when he invented and first produced the familiar upright pianoforte—portable grand as he then called it. He patented it in America his father Isaac Hawkins taking out the patent for him in England in the same year 1800.

There had been upright grand pianos as well as upright harpsichords the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell an Irish piano maker had in 1798 tried a similar experiment with a square piano to be repeated in later years by W F Collard of London but Hawkins was the first to make a piano with the strings descending to the floor the keyboard being raised and this although at the moment the chief was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument is in a complete iron frame independent of the case and in this frame strengthened by a system of iron resistance rods combined with an iron upper bridge his sound board is entirely suspended. An apparatus for tuning by mechanical screws regulates the tension of the strings which are of equal length throughout. The action in metal supports anticipates Wornum's in the checking and still later ideas in a contrivance for repetition. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the tall cabinet pianoforte with hinged sticker action in 1807. All that he could however patent in it was the simple damper action turning on a pivot to relieve the dampers from the strings.

steps for production of the piano were taken by Robert Wornum who in 1813 visited Paris and saw the Erard action. He was so impressed by it that he entered for a patent in 1814 a piano with a three year lease when Wornum died. The principle of the Erard action was the

FIG 21—ERARD'S DOUBLE ESCAPEMENT ACTION (1821)

The escapement of the action is effected by a hopper which is placed in front of the key hammer. The hammer is raised by the key hammer and the hammer is raised by the key hammer.

into Paris by Pleyel and Iape and thence into Germany and America (Pleyel exhibited a small upright piano in Paris in 1813 but Pierre Erard did not turn his attention to upright pianos until 1831).

Early in the 19th century William Allen a young man in the employ of the Stodarts devised a metal system of framing intended primarily for compensation but soon to become in other hands a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by atmospheric changes by compensating tubes and plates of the same metals guaranteeing their stability by a cross bolting of stout wooden bars and a metal bar across the wrest plank. Allen consulted Stodart's foreman Thom and Allen and Thom patented the invention in January 1820. The firm of Stodart at once acquired the patent.

We now arrive at an important epoch in pianoforte construction—the abolition of the wooden construction in favour of a combined construction of iron and wood the former material gradually asserting pre-eminence. Allen's design is shown in fig 24. The long bars are really tubes fixed at one end only those

FIG 22—STEINWAY'S GRAND PIANO ACTION (1884)

The double escapement as in Erard's (fig 21) but with shortened balance and a check. The hopper escapes from under the hammer owing to the bell crank lever coming into contact with the set-off button.

of iron lie over the iron or steel wire while those of brass lie over the brass wire the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings without danger to the durability of the case and frame. In 1821 a fixed iron string plate the invention of one of Broadwood's workmen Samuel Hervé, was applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even

the iron and the return of the hammer. The hammer was exposed to the air and the return of the hammer was exposed to the air. The hammer was exposed to the air and the return of the hammer was exposed to the air. The hammer was exposed to the air and the return of the hammer was exposed to the air.

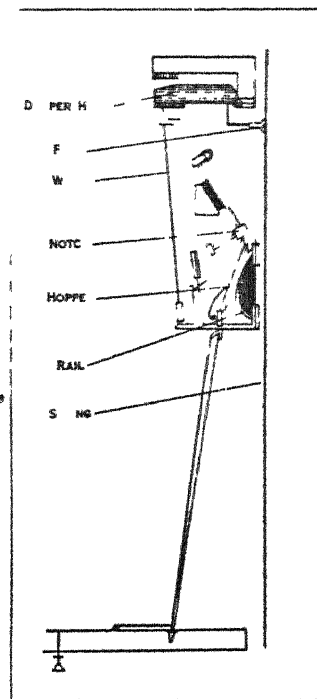

FIG 23—WORNUM'S UPRIGHT ACTION (1826) ORIGINAL OF THE NOW UNIVERSAL ACTION IN UPRIGHT PIANOS

grand pianoforte to depend practically upon iron in which to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars there should be no bar parallel to the strings except a bass bar while another flanged resistance bar as an entirely novel feature crossed over the strings from the bass corner of the wrest plank to a point upon the string plate where the greatest accumulation of tension strain was found. After the Great Exhibition of 1851 he employed an ordinary straight bar in the middle of his concert grand scale his smaller grands having frequently two such as well as the long bass bar. After 186 he covered his wrest plank with a thick plate of iron into which the tuning pins screw as well as into the wood beneath thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string.

The introduction of iron into pianoforte structure was differently and independently effected in America the fundamental idea there being to use a single casting for the metal plate and bars instead of forging or casting them in separate pieces. Alphaeus Babcock was the pioneer of this kind of metal construction. He also cast an iron ring for a square piano in 1825 which although not a success gave the clue to a single casting resistance framing successfully accomplished by Conrad Meyer in Philadelphia in 1833 in a square piano which still exists and was shown in the Paris Exhibition of 1878. Meyer's idea was improved upon by Jonas Chickering (1797-1853) of Boston who applied it to the grand piano as well as to the square since which time this prin

could have been universally adopted.

We have now considered over or cross stringing by which the division of the strings is made to cross over the error part of the case—over the length in instance of a long or has been the first in a parallel scale and in the next step the strings extend further over bridge pressure on the curbs. In the case of clavichords were sometimes

used in the case of a very small part of the strings (the strings in the case of a very small part of the strings) and in the case of a very small part of the strings

The first attention for the overstringing in the piano was made by the celebrated flute player and inventor Theobald Boehm who carried it beyond theory in London in 1811 by employing a small firm located in Cheap Id. Geroch & Wolf to make some overstrung pianos for him. Boehm expected to gain in tone. Pape an ingenious mechanic in Paris tried a like experiment to gain economy in dimensions his notion being to supply the best piano possible with the least outlay of means. Tomkin on in London continued Pape's model but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano made by Lichtenthal of St.

Petersburg overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. Later in 1835 Henry Engelhard Steinway (originally Steinweg 1797-1871) who had emigrated from Brunswick to New York in 1849 and had established the firm of Steinway & Sons in 1853 in that city effected the combination of an overstrung scale with the American iron frame which exhibited in grand and square instruments shown in London in the International Exhibition of 1862 excited the attention of European pianoforte makers leading to important results.

It would be inaccurate to say that no outstanding developments have taken place in pianoforte construction during the last fifty years but few new principles have been discovered and improvement has taken place almost entirely in the direction of applying in greater and greater measure scientific knowledge to methods and practices previously empirical (see *PIANOFORTE MANUFACTURE*) thus resulting in improvement in tonal volume and purity.

Summing up matters it may be said that the modern pianoforte retains six important characteristics of the clavichord in that it has an independent sound board (the ends of the strings are not fastened to it) dampers to prevent vibration of the strings not in use fluffing cloth to deaden the vibration from the ends of the strings beyond the bridges groups of three strings tuned in unison and a tone production which depends upon a blow instead of a plucking (as in the spinet and harpsichord).

Five of the ideas developed in the harpsichord have also sur-

vived or have been revived from time to time namely the sustaining pedal the celeste felt for soft playing the transposing key board the soft stop for practising very quietly and the double manual (viz. as recently introduced by Emanuel Moor).

As regards the sustaining pedal the importance of this cannot be over estimated for not only does it allow of harmonies being maintained when necessary without holding the keys down but it modifies the tone quality by allowing all strings to take part simultaneously by means of their resonance. Moreover the sound board is encouraged to increase its amplitude of vibration thus increasing the tonal volume which in skilful hands can be made to reach a maximum intensity of over twenty times that of the most powerful harpsichord. Contrariwise the tone can be attenuated and diminished by means of the soft pedal which brings the hammers nearer the strings or (as in the case of grand pianos) shifts the hammers so that they strike two instead of three strings. The celeste pedal and soft stop devices both involve the introduction of a strip of felt between the strings and the hammers at the point of contact thus reducing the force of the blow. For school pianos used for practising almost continuously throughout the day the soft stop is a most useful adjunct and when properly designed need not interfere unduly with the touch of the instrument.

The transposing device in turn is now becoming popular on player pianos which are being increasingly used for accompaniment purposes. It is obviously a great advantage to be able to suit the requirements of any particular voice in this way and the means of doing so are easily provided. In the ordinary instrument on the other hand it is difficult to keep transposing devices in perfect order owing to the necessity for shifting the keys relative to the action a movement which upsets the delicate regulation of the repetition and renders the device unsatisfactory.

Finally the double keyboard as invented by Emanuel Moor represents a really important development extending the resources of both performer and composer to an astonishing degree. Such a revolutionary departure will doubtless take time to become commercially possible but the most weighty musical opinion is entirely in its favour. Briefly stated the second keyboard lies just behind and above the normal standard notes and operates those strings which are an octave higher. Consequently it is possible to play extended chords arpeggios and double octaves with great facility. There is also an octave coupler which further increases the possibilities of the instrument from the point of view of volume. To what extent the principle will ever secure general adoption it would be rash to prophesy but as to its ingenuity and musical value there is no room for doubt.

The principles discovered in the early actions (Erard 1821 and Robert Wornum 1826) still stand firm, and all subsequent improvements have been built thereon. The separate parts of the modern action are produced by automatic machinery and assembled by hand with great skill and accuracy. The pianoforte

\* **PIANOFORTE MANUFACTURE** There are eighty eight notes in the full compass keyboard of the pianoforte which gives a range of  $4\frac{1}{2}$  octaves. The fifty second note from the bass end of the scale is called Pitch C and serves as the standard from which all the other are used. Since each note has to vibrate twice as fast as the note of the same name an octave below and there are twelve semitones to the octave it follows that the semitone ratio from note to note must be the twelfth root of 2 namely 1.05946 which is a geometrical progression giving the now generally adopted equal temperament tuning. Purely mathematical considerations make it essential that the string lengths should also proceed in geometrical progression but in a slightly smaller octave ratio than 1. In Germany the ratio most favoured is 1.875 and in Great Britain 1.891. Both of these ratios approximately allow of half size increases in the gauge of wire used.

FIGS 1 2 & 3—METHODS OF CONNECTING STRINGS TO SOUNDBOARD

twice per octave without departing far from the uniform tension initially decided upon. The English Music Wire Gauge advances one thousandth of an inch in diameter per half size while the New Westphalian Gauge advances 0.025 millimetre per half size but there are irregularities in the English Gauge at various places for reasons apparently unknown.

In small instruments whether grands or uprights it is impossible to carry theoretical string lengths throughout the piano and compromises have to be made by shortening and thickening them in order to maintain the necessary high tension. Since short

period English felt used where there is the quill. It required its resilience being equal to the German. In modern hammer making the action is the rubber wheel the hammer dimension remains the same. The hammer has a hammer beneath the nose of the hammer which is at the actual point of contact. In the hammer the hammer is secured an even grade of case with no audible break between the treble and bass string.

**The Action**—The hammers are actuated by a system of levers known as the action which is now made by firms specialising in this unit alone rather than by the piano manufacturer himself. The nose of the hammers rest at a distance of two inches from the strings but if a note is held down after having been played the hammer is checked when it has rebounded five eighths of an inch so that the blow can be repeated rapidly. When the key is half way down the felt damper is lifted from the string and remains lifted until the key is released.

**Pedals**—The tone is modified by means of two pedals the left hand pedal taking the hammers nearer to the string and thus decreasing the force of the blow. Sometimes the whole action is shifted to the right so that the hammer only strikes two strings instead of three. The right hand pedal lifts all the dampers from the strings so as to sustain harmonies as long as required and not merely for increased power. In America a central pedal is often added called the Sostenuto which instead of lifting all the dampers affects only those which happen to be already lifted keeping them so until the pedal is released. Thus one is able to sustain a chord leaving the hand free for other notes.

The ideal point of contact for the dampers is at the same place as the striking point and in grand pianos this is approximately arranged the dampers lying along the strike line above the strings and operated by gravity only. In upright pianos a position just under the strike line is favoured such actions being known as under damper and the pressure obtained by springs. The cheaper piano is sometimes provided with an older type wherein the damper is operated by gravity at a point just above the hammers. This is known as the over damper action and although the vibrations of the strings are of less amplitude above the hammer line than below it a well made over damper action is still in favour by certain Continental makers of repute owing to its more effective silencing of the harmonics.

**Touch**—The depth of touch for the keys has been standardised in all countries at 9 millimetres with an additional millimetre to allow of the locking of the check and the free escapement of the Jack lever. The pivoting of the key has to be so placed as to give the correct amount of lift at the other end usually about 6 millimetres but varying a little with the different makes of action. The best touch is secured if the keys slope backwards a little when at rest becoming exactly level when half depressed. At this point begins the extra load due to the lifting of the dampers but the momentum already gained is sufficient to render it unnoticeable. A touch weight is used during the regulating of the action so that when it is placed upon the end of the key and suddenly released the force exerted is just sufficient to make the note sound faintly. This dead weight of touch is not standardised but averages 90 grammes in the bass down to 60 grammes in the treble.

**Frame**—The iron frame which takes most of the load exerted by the pull of the 220 strings is cast in one piece at the foundry from an iron pattern which has been made 1 per cent larger than the finished frame in order to allow for the contraction of the casting during cooling.

**Tuning Pins**—The tuning pins of mild steel about 7 millimetres in diameter are driven into a wrest plank of quartered beech or maple sometimes of ply construction to prevent splitting. The holes are bored slightly smaller than the pins a ratio of 15:17 giving the correct amount of tightness. Since the plank is bolted to the iron frame and glued to the wooden back it follows that the load is shared between the frame and the back the tendency in modern construction being to eliminate the wooden back alto-

gether. It was formerly covered with a web of iron in order to hold the hammer driven the tuning pins. This method has proved very successful in both upright and grand pianos. The method above described is the one used in both upright and grand pianos.

For the upright piano the metal wrest plank has proved to be the best. The wrest plank being held in position by the back of the plank.

FIG 4—STEINWAY GRAND CASE WORK SHOWING PARTS

**Standardisation**—The similarity in methods and design of the leading manufacturers in all countries is accounted for by the necessity for standardisation of the keyboard height from the floor, the provision of room for the knees, the situation of the pedals and the natural laws controlling the vibration of stretched string. In the upright piano the wooden back forms a convenient base to which the ends of the case are glued besides being the means for securing rigidity for the edges of the sound board and a support for both iron frame and wrest plank.

The peculiar form of the grand piano enables an immensely strong inner rim to be built up in one continuous bend into which bracings are dove tailed and to which the key bottom (supporting the keyboard) is secured. This inner rim on which the sound board and iron frame are fastened may be six inches deep and from 1½ to 1¾ thick. Additional rigidity is further provided by gluing this unit to an outer rim also of ply formation about a foot deep and from 1 to 1½ thick. The skeleton formation of the case work of a large Steinway grand is shown in fig. 4 but it must be remembered that the lateral stiffness of such a structure varies inversely as the cube of its length and therefore small grands do not need such elaborate reinforcement the very smallest (4 ft 3 in to 4 ft 6 in in length) often having no bracings at all. (S A H)

See the BIBLIOGRAPHY under PIANOFORTE also *Grove's Dictionary of Music and Musicians* (1927-28)

#### PIANOLA see PLAYER PIANO

**PIANOSA** (anc. *Planasia*) an island of Italy belonging to the province of Leghorn and forming part of the commune of Campo nelle Elba from which it is 11 m SW. Pop. (1911) 908. As its name indicates it is quite flat and the highest point is only 95 ft above sea level. Its area is 6 sq m. The discovery of numerous fossilized bones of animals show that it was still united to the mainland in the quaternary period. Traces of human habitation in the neolithic period have been found. Augustus banished to it his grandson Agrippa Postumus and some ruins of baths near the harbour still bear his name. It was depopulated in 1553 by the Turkish fleet and only resettled in 1835.

**PIARISTS**, the popular name of a Catholic educational order the clerici regulares scholarum *piarum* the Pauline Congregation of the Mother of God founded by Joseph of Calasanza at Rome in the beginning of the 17th century. Here he organized, in 1607 a brotherhood which ultimately in 1617 became an independent Congregation numbering at that time fifteen priests under Calasanza as their head. To the three usual vows they added a fourth that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV and had all the privileges of the mendicant

**Spanish Examples.**—The earliest specimen of the kind is *La Vida de Lazarillo de Tormes y de sus fortunas y adversidades*: an anonymous tale long attributed, on insufficient grounds, to Diego Hurtado de Mendoza (qv). The authorship of this brilliant book and the circumstances of its publication are obscure, however it was certainly issued not later than 1554 (in three editions) and was thrice reprinted before 1559 when it was placed on the Index. Imitations of so successful a story were inevitable and as early as 1555 there appeared at Antwerp *La segunda parte de Lazarillo de Tormes* an anonymous sequel.

Salmon *L'Art de l'Art et de l'Art* (1920) (I. A. R.)

**PICAYUNE**, the name in Florida and Louisiana of the Span  
ish half real =  $\frac{1}{16}$  of a dollar 6½ cents and hence used of the  
United States 5 cent piece from the French *picayon* an old  
copper coin of Piedmont and possibly related to the Italian  
*piccolo* little small. In America the word is used of anything  
trifling or contemptible.

**PICCININO, NICCOLO** (1586-1444) Italian *condottiere*  
born at Perugia. He served under the Visconti of Milan in  
campaigns against Francesco Sforza from 1435 to 1444.

**PICCINNI, NICCOLA** (1728-1800) Italian composer was  
born at Bari Naples on Jan 16 1728. He was educated under  
Leo and Durante at the Conservatorio di Sant Onofrio in Naples.  
His first opera *Le Donne dispettose* was produced in 1755 and  
in 1760 he composed at Rome *La Cecchina ossia la buona  
Figliuola* an *opera buffa* which attained a European success. It  
was followed by many others one of which also an *opera buffa*.  
*Il Viaggiatore* (Naples 1774) had nearly as great a success as  
*La Cecchina*. In 1776 Marie Antoinette invited him to Paris. He  
had married in 1756 his pupil Vincenza Sibilla a singer whom  
he never allowed after her marriage to appear on the stage. All  
his next works were successful but unhappily the directors of the  
Grand Opéra conceived the mad idea of deliberately opposing  
him apparently against his will to Gluck by persuading the two  
composers to treat the same subject—*Iphigénie en Tauride*—  
simultaneously. The Parisian public now divided itself into two  
rival parties which under the names of Gluckists and Piccinnists  
carried on an unworthy and disgraceful war. Gluck's *Iphigénie*  
was first produced on May 18 1779. Piccinni's *Iphigénie* followed  
on Jan 23 1781 and though performed seventeen times was  
soon forgotten. Of the works of Piccinni's Paris period the  
best is *Didon* (1783) which kept the stage for half a century. In  
1789 after the outbreak of the French Revolution Piccinni re  
turned to Naples where he was at first well received by King  
Ferdinand IV, but the marriage of his daughter to a French  
democrat brought him into irretrievable disgrace. For nine years  
after this he maintained a precarious existence in Venice, Naples  
and Rome but he returned in 1798 to Paris where a small place  
was found for him at the Conservatoire. He died at Passy, Paris  
on May 7 1800.

See P. L. Guigney *Notice sur la vie et les ouvrages de Niccolò  
Piccinni* (Paris, 1801), E. Demourestres, *La Musique française au  
18<sup>e</sup> siècle* Gluck et Piccinni, 1774-1800 (Paris, 1872) E. Blom  
*Stepchildren of Music* (1926) For a list of his operas which number  
over 80, see *Rivista musicale italiana* viii 75.

**PICCOLO**, a small flute of less than half the dimensions of  
the large concert flute and pitched an octave higher. The prin  
ciples of construction and the acoustic properties are the same for  
the piccolo as for the flute with the exception that the piccolo  
does not contain the additional tail piece with the extra low keys  
which give the flute its extended compass.

**PICCOLOMINI**, the name of an Italian noble family  
prominent in Siena (q.v.) from the beginning of the 13th century  
onwards. In 1300 Engheberto d'Ugo Piccolomini received the fief  
of Mortertan in Val d'Orcia from the emperor Frederick II as  
a reward for services rendered. They obtained great wealth  
through trade and established counting houses in Genoa Venice  
Aquila Trieste and in various cities of France and Germany.  
Supporters of the Guelph cause in the civil broils by which Siena  
was torn they were driven from the city in the time of Manfred  
restored after the Angevin victories expelled again during the brief  
reign of Conradin and again restored with the help of Charles  
of Anjou. Their commercial influence passed to the Florentines.  
Many members of the house were distinguished ecclesiastics gen  
erals and statesmen in Siena and elsewhere two of them were  
popes viz Aeneas Silvius Piccolomini (Pius II q.v.) and Fran  
cesco Piccolomini (Pius III q.v.).

See Richter *Die Piccolomini* (Berlin 1874) A. Lisini and A. Lib  
crati *Albero della famiglia Piccolomini* (Siena 1899) and articles by  
A. Lisini in the *Miscellanea storica senese* 3rd series 12 and 4th series  
17 and 189.

**PICCOLOMINI, OCTAVIO**, PRINCE (1599-1656) duke  
of Amalfi. Austrian general was born on Nov 11 1599 in Flor  
ence and carried a pike in the Spanish service at the age of six  
teen. On the outbreak of the Thirty Years War he served in  
Bohemia and Hungary then in Spain and Italy. In 1627 he re  
entered the Imperial service as colonel and captain of Wallen  
stein's lifeguard. He was disgraced for practising extortion at  
Stargard in Pomerania but his adroitness soon secured him the  
rank of colonel of horse and foot. In the Mantuan War Pic  
colomini acted both as subtle diplomatist and as plundering soldier  
of fortune when Gustavus Adolphus invaded Germany.

Piccolomini was interned at Ferrara as a hostage for the ratifi  
cation of a treaty but joined in urging Wallenstein's reappoint  
ment as commander in chief. He was not immediately promoted  
on the duke's reappearance and served under General Holk  
an officer brought in from the Danish service in the preliminary  
operations and in the battle of Lutzen. After Lutzen the Emperor  
made Piccolomini a *general feldwachtmeister*. At the same time  
however Holk was created a field marshal at Wallenstein's in  
stance much to his rivals' chagrin. In 1633 Piccolomini com  
manded an important detachment posted at Koniggratz to bar the  
enemy's advance from Silesia into Bohemia. In May he accom  
panied Wallenstein on his advance into Silesia but disapproving  
of the duke's policy joined in a military conspiracy which ended  
in the murder of Wallenstein (Feb 29 1634). Piccolomini's own  
part in the tragedy is commemorated in Schiller's *Wallenstein*.  
His material rewards for his activities in connection with the  
downfall of Wallenstein were his marshal's bâton 100 000 gulden  
and the beautiful estate of Nachod in the Riesengebirge.

In 1638 Piccolomini was made a count of the empire and in  
1639 won a great victory over the French (relief of Thionville  
July 7 1639) was rewarded with the office of privy councillor  
from the emperor and with the dukedom of Amalfi from the  
king of Spain. But instead of being appointed as he hoped  
Gallas's successor he was called in to act as *ad latus* to the Arch  
duke Leopold Wilhelm with whom he was defeated in the second  
battle of Breitenfeld in 1642. After this he spent some years in  
the Spanish service, being granted the title of grandee and the  
order of the Golden Fleece. Having reentered the Imperial  
army, he was again disappointed of the chief command by the  
selection of the brave veteran Peter Melander Count Holzapfel,  
but in 1648 he was at last appointed lieutenant-general of the  
emperor, and thus conducted as generalissimo the final campaign  
of the Thirty Years War at the end of which he was made prince.  
He died on Aug 11 1656. He left no children (his only son  
Josef Silvio, the "Max" of Schiller's *Wallenstein* was murdered

It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated

**PICKENS, ANDREW** (1739-1817) American soldier in the Revolutionary War was born in Paxton Pa on Sept 19 1739 His family settled at the Waxhaws (in what is now Lancaster county) S C in 1752 He fought against the Cherokees in 1761 as a lieutenant In the Revolutionary War he rose to brigadier general (after Cowpens) in the South Carolina militia On Feb 14 1779 with 300-400 men he surprised and defeated about 700 Loyalists on Kettle Creek Wilkes county Ga and later in the same year at Tomassee defeated the Cherokees who were allied with the British Upon the surrender of Charleston (May 1780) he became a prisoner on parole which he observed rigidly until contrary to the promises made to him Maj James Dunlap plundered his plantation he then returned to active service His command (about 150 men) joined Gen Daniel Morgan immediately before the battle of Cowpens in which Pickens commanded an advance guard (270-350 men from Georgia and North Carolina) and twice rallied the broken American militia for his services Congress gave him a sword With Col Henry Lee he harassed Lieut col Banastre Tarleton who was attempting to gather a Loyalist force just before the battle of Guilford court house and with Lee and others he captured Augusta (June 5 1781) after a siege At Euclid Springs (Sept 8 1781) he commanded the left wing and was

wounded. In 18 he d... war he wa... 95 wa... strict SC on Aug... houn an... (179-183) served a... nd was governor of South Carolina. See E B P... vol vii pp 137-138.

**PICKEREL**, the name used especially in America where there are several species which never reach a large size for certain small pike (*Esox lucius*) the only specie represented are usually termed jack.

THE EASTERN PICKEREL. AVERAGE LENGTH ABOUT 2 FEET

### PICKERING EDWARD CHARLES (1846-1919)

American physicist and astronomer was born in Boston on July 19 1846. He was graduated in 1865 in the Lawrence Scientific school of Harvard where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology where he established the first laboratory in America in which students were instructed by actual contact with physical instruments and measurements. In 1876 he was appointed professor of astronomy and director of the Harvard college observatory. In 1878 when most observatories were devoting themselves to the old astronomy of position Prof Pickering who was a physicist rather than an old school astronomer chose as his particular field of labour the photometry of the stars thus presaging the trend of the new astronomy along lines of physics. He invented the meridian photometers (see PHOTOMETRY Stellar) with which the brightness of more than 45000 stars has been measured at Cambridge and Arequipa (Peru) observatories and the resulting system generally adopted as an international standard. Prof Pickering personally made more than 150000 photometric settings.

Through the establishment of an observatory at Arequipa (1891) after two years of study it became possible to include measurements made on the stars throughout the Southern heavens within the scope of the Harvard college observatory's work.

The work of the observatory under Prof Pickering may be summarized as including photometry in which photometric magnitudes for 80000 stars have been determined a scale of photographic magnitude a system of classification of variable stars and a system of stellar spectroscopy which has been universally adopted. As a result of Pickering's work the Harvard photographic library of stars contains more than 250000 photographic plates. He died at Cambridge Mass on Feb 3 1919.

For bibliography and further biographical material see *Biographical Memoirs of National Academy of Sciences* vol vii pp 5-57. See also *Proceedings of the American Academy of Arts and Sciences* vol lvi pp 502-506 (Boston 1921) *Monthly Notices of Royal Astronomical Society* vol viii pp 360-365.

### PICKERING, TIMOTHY (1745-1829)

American politician was born at Salem Mass on July 1 1745. He graduated

at Harvard in 1763. He was admitted to the bar in 1766. He was active for ever... 95 was a representative in... strict SC on Aug... houn an... (179-183) served a... nd was governor of South Carolina. See E B P... vol vii pp 137-138.

He was a prominent member of the group known as the Essex Junto—he strongly opposed the purchase of Louisiana and opposed the War of 1812. He died at Salem Mass on Jan 9 1829.

The standard biography is that by his son Octavius Pickering (1831-1886) and C W Upham *The Life of Timothy Pickering* (Boston 1868-1870). In the library of the Massachusetts Historical Society at Boston there are 6 manuscript volumes of the Pickering paper an index to which was published in the *Collections of the Society* 6th series vol viii (Boston 1896).

His son JOHN PICKERING (1771-1846) graduated at Harvard in 1796. He wrote on the languages of the North American Indians. He was a founder of the American Oriental Society and published a *Comprehensive Dictionary of the Greek Language* (1806).

Timothy Pickering's grandson CHARLES PICKERING (1805-1888) was naturalist to the Wilkes exploring expedition of 1838-42 and in 1843-45 travelled in East Africa and India.

### PICKERING, WILLIAM HENRY (1858-1938)

American astronomer was born in Boston Mass on Feb 15 1858 and in 1879 graduated at the Massachusetts Institute of Technology. He served as an assistant and instructor in physics at his Alma Mater from 1880 to 1887 and then became an assistant in astronomy at the Harvard college observatory. In 1889 he was made assistant professor of astronomy. He led expeditions for observing total solar eclipses to Colorado 1878 Grenada West Indies 1886 California 1889 Chile 1893 and Georgia 1900. While in southern California in 1889 he selected the Mt Wilson site and established a temporary observatory there. In 1891 he established the Arequipa station of the Harvard observatory in Peru. He also established a meteorological station at an altitude of 16650 ft upon Mt Chachani, and accomplished the ascent of El Misti 19200 feet. He surveyed and determined the altitude of many other Peruvian mountains and returned to the United States by way of the Straits of Magellan in 1893. In 1894 he erected the observatory and telescope for Dr Percival Lowell (qv) at Flagstaff Ariz and in 1900 erected a station for the Harvard observatory at Mandeville Jamaica in the West Indies. In 1899 he discovered Phoebe 9th satellite of Saturn.

and explained its contrary revolution. The doubtful 11th satellite Themis which was announced in 1903, remain unconfirmed. In 1904 he again went to California to make observations of the moon in 1905 to Hawaii and in 1906 to the Azores to compare their crater formations with those in the moon. His work in planetary photography and photometry was especially notable. In later years he turned more and more to the study of Mars.

Besides many papers in astronomical journals (see especially *Popular Astronomy*) he wrote *A Walking Guide to the Mt. Washington Range* (1887), *Investigations in Astronomical Photography* (1895), *Visual Observations of the Moon and Planets* (1901), *An Atlas of the Moon* (1901), *Lunar and Hawaiian Physical Features Compared* (1906), *A Search for a Planet Beyond Neptune* (1909), *A Statistical Investigation of Cometary Orbits* (1911), *Mars* (1911).

**PICKERING**, urban district and town in the North Riding of Yorkshire, England, 5 m N.E. by N from York by the L.N.E. railway on which it is an important junction. Pop. (1911) 668. The town lies at the foot of the York moors at the entrance to one of the river ways into the Vale of Pickering. It is the centre of an agricultural and pastoral area with a broad belt of arable land in the vale given to cereal and fodder crops. North of Pickering is a moorland grazing area. Agricultural implements are manufactured there and limestone and freestone are quarried in the vicinity.

A castle existed at Pickering before the Conquest and the present ruin on a hill to the north of the town is partly Norman but mainly 14th century in style. A fragmentary keep and several towers remain. It was the prison of Richard II before his confinement at Pontefract. During the Civil War it was held by the royalists and suffered greatly in siege.

**PICKETING** see TRADE UNIONS

**PICKETT, GEORGE EDWARD** (1835-1885) American Confederate soldier born at Richmond, Va. Jan. 5, 1835. Upon graduation at West Point in 1856 he was assigned to the 8th United States Infantry, served with distinguished valour in all the battles of Gen. Scott in Mexico including the siege of Vera Cruz and the storming of Chapultepec where it is said he was first to scale the parapets and unfurl the American flag over the castle. After peace was restored Pickett was transferred to Washington Territory where he was destined to play an important role in the north-west boundary controversy. In 1859 he was ordered to occupy San Juan island where he prevented the landing of a superior force of British troops. On the outbreak of the Civil War he resigned his command (June 1861) and offered his services to the Confederacy. He was commissioned captain and after a short time was made a colonel. In Feb. 1862 he was appointed a brigadier general and assigned to the command of a Virginia brigade of infantry. During that year he rendered able service in the battles of Williamsburg, Seven Pines, Gaines Mill and Fredericksburg. While leading his men at Gaines Mill he was severely wounded but upon returning to his command in September he was made a major general. At Gettysburg his division was held in reserve until July 3 when it led the attack on Cemetery Hill. The charge of Pickett's men is one of the most famous episodes of military history. Over three quarters 3,500 officers and men out of 4,500 were left on the field. He subsequently commanded the Confederate forces in North Carolina but after the failure to take Newbern he turned north to defend Petersburg. His troops participated in the assault on Grant's line at Cold Harbor and performed excellent service in the closing campaign of 1865 at Dinwiddie court house and Five Forks. After the Civil War he went to Richmond and later to Norfolk where he was engaged in the insurance business. His death occurred in Norfolk on July 30, 1875.

See La Salle Corbell Pickett, *Pickett and his Men* (1899, rev. ed. 1913) and A. C. Inman, editor, *Soldier of the South: Gen. Pickett's War Letters to His Wife* (1928).

**PICKFORD, MARY** (1892-) (stage name of Gladys Smith), American motion picture actress born at Toronto, Canada, April 8, 1892. Her first stage appearance was at the age of five. At eight she went on tour. She went to New York under the auspices of Belasco, creating the part of Betty Warren in *The Warrens of*

W. Griffith as an extra but she returned to Belasco taking the part of Juliet in *A Good Little Devil* at the Republic theatre in New York. In 1913 she returned to the screen with Famous Players Company and rose to the first rank. In 1916 the Mary Pickford Film Corporation was organized and she received a salary higher than paid to any other motion picture actress. In 1918 she became an independent producer and the following year was prime mover in forming the United Artists Corporation. She married Douglas Fairbanks in 1920, was divorced in 1935 and married Charles Rogers in 1937.

**PICKLE** In the wider sense the term pickle is applied to any saline or acid preservative solution in the narrower to vegetables preserved in vinegar. The word appears to be an adaptation of the Dutch *pekel* brine pickle cf. Ger. *Pökel*. A solution of copper or zinc sulphate is used as a pickle for railway sleepers or other wood. A brine containing salt and saltpetre as a preservative for meat, lime water as pickle for eggs. Domestic pickles are made from small cucumbers, onions, cauliflowers, cabbage, mangoes, unripe walnuts and other fruits and vegetables by either steeping or boiling them in salt brine and vinegar.

**PICO**, an island in the Atlantic ocean belonging to Portugal forming part of the Azores archipelago, pop. about 25,000 and area 1,500 miles. Pico rises to the height of 7,613 feet. The soil is of volcanic origin. The island was formerly famous for its Fayal wine (Fayal is however an adjacent island) but in 1855 the vines were destroyed by disease. Similar destruction affected the fruit trees (orange) and a period of emigration followed. The distress was alleviated by the planting of fig trees and the cultivation of apricots. The chief town is Lagens do Pico.

**PICO DELLA MIRANDOLA, GIOVANNI**, COUNT (1463-1494) Italian philosopher and writer, the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory not far from Ferrara, afterwards absorbed in the duchy of Modena, was born on Feb. 4, 1463. In his fourteenth year Pico went to Bologna where he studied for two years and was much occupied with the Decretals. He then spent seven years wandering through Italy and France and collecting a precious library. Besides Greek and Latin he knew Hebrew, Chaldean and Arabic and his Hebrew teachers introduced him to the Kabbalah. He settled in 1486 at Rome where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of philosophy and theology but the pope prohibited them and Pico had to defend the impugned theses in an elaborate *Apologia*. His personal orthodoxy was subsequently vindicated by Alexander VI. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries and it was by him that Reuchlin was led into the same delusive path.

In his 8th year Pico published the *Heptaplus*, a mystical exposition of the Creation. Next he planned a great sevenfold work against the enemies of the Church of which only the section against astrology was completed. After leaving Rome he again lived a wandering life, often visiting Florence to which he was drawn by his friends Politian and Marsilius Ficinus and where also he came under the influence of Savonarola. Three years before his death he parted with his share of the ancestral principality and designed when certain literary plans were completed to give away all he had and wander barefoot through the world preaching. But these plans were cut short by a fever which ended in his death at Florence on Nov. 17, 1494.

His works were published at Bologna in 1496 by his nephew with a biography which was translated by Sir Thomas More as *Life of John Pico, Earl of Mirandola* in 1510. See Walter Pater's *Renaissance* (1878) the study by J. Rigg prefixed to the reprint of More's *Life in the Tudor Library* (1890), Mortetani *La filosofia cabalistica di Pico della Mirandola* (Empoli, 1898) and A. Levy *Die Philosophie Picos della Mirandola* (1908).

**PICRIC ACID** or **LYDDITE**, is a yellow crystalline solid melting at 122.5°C and owes its name to the intensely bitter and persistent taste of its yellow aqueous solution. As experiments regarding the use of picric acid as a high explosive were once conducted at the town of Lydd (Sussex) the name Lyddite became attached to the acid. The term melinite is employed in France

explosive As its graphic formula (inset) indicate it is a benzoid derivative with three hydrogen atoms of the benzen nucleus replaced by nitro (NO) groups and one replaced by a hydroxyl (OH) group whence its name and formula  $\text{C}_6\text{H}_2(\text{NO})_3\text{OH}$  It is a typical example of a nitro compound of the aromatic series and was formerly employed as an acid dye tuff giving yellow shades on wool or silk Although acting as a poison when administered in quantities exceeding a few milligrams its saturated aqueous solution may safely be applied to burns and scalds with the object of subduing the pain which it effects by paralysing the sensory nerve endings

The ordinary method of manufacturing picric acid is to dissolve phenol in strong sulphuric acid thus making a phenolsulphonic acid  $\text{C}_6\text{H}_5\text{OH} + \text{H}_2\text{SO}_4 = \text{HO C}_6\text{H}_4\text{SO}_3\text{H}$  which on treatment with a moderate excess of nitric acid regenerates sulphuric acid and at the proper temperature gives finally trinitrophenol This separates as an oily liquid which becomes solid on cooling It is washed with cold water to remove excess of acids and then dissolved in hot water from which it crystallizes in yellow scales plates or needles depending on the concentration of solution The picrates of ammonia and of the alkali metals sodium and potassium are most soluble whereas the lead salt and a few others are sparingly soluble in water Certain organic bases such as acridine give more insoluble salts than metals When heated above its melting point picric acid puffs or burns with a smoky flash a small amount may sublime as a yellow powder This burning does not appear to be dangerous when only small quantities are dealt with unless the external heating be rapid and extensive so that the whole bulk under experiment is heated up in that case the simple burning passes over into a kind of detonating decomposition The metallic salts of picric acid are most liable to this violent form of explosion in fact it is almost the only form of explosion they exhibit either on heating or under percussion The picrates of lead bismuth and other heavy metals are extremely sensitive to friction or percussion as well as heating especially when dry The pure acid itself is not dangerously sensitive to percussion although a powerful and quick glancing blow will often induce decomposition The explosion of a very small amount of a picrate—as the lead or potassium salt—in contact with the acid especially if the latter be in a compact state generally induces a complete detonation At one time picric acid was much in favour either as an ingredient of an explosive mixture with some special objective use or alone Among the mixed explosives containing picric acid may be mentioned Brugeres powder a mixture of 54 parts of ammonium picrate and 45 of potassium nitrate Designolles powder potassium picrate potassium nitrate and charcoal and Emmensite of similar composition suggested by Mr Emmens USA Many others were designed for blasting or similar purposes (W R Ho)

**PICRITE**, in petrology an intrusive igneous rock of ultra basic composition somewhat similar to peridotite (q.v.) The name given by Tschermak in 1866 is derived from *πικρός* bitter owing to the high percentage of magnesia (bitter earth) these rocks contain The picrites are dark heavy rocks largely composed of olivine and augite with a small but variable amount of plagioclase feldspar Hornblende and biotite may also be present The picrites usually occur in sills or sheets and seldom in large plutonic masses (unlike peridotites) Varieties of picrite include augite enstatite and hornblende picrite

The minerals of picrites are very frequently decomposed Serpentine partially or wholly replaces olivine while hornblende (pilitite) talc and chlorite appear as secondary products after the same mineral Augite passes into hornblende or chlorite and the essential feldspar is often represented by epidote prehnite and white mica In some picrites as in the peridotites a lustre mottling is given by the poikilitic inclusion of olivine grains in large crystals of augite or hornblende In the porphyritic varieties a residual brown glass may be present Such rocks are known as picrite porphyrites

picrites of the Midland valley of Scotland and of the type localities in Moravia contain interstitial anatexite and are closely related to the teschenites with which they are associated Other picrites are more clearly calc alkaline being associated with diorites or dolerites The hornblende picrites of Carnarvonhire Anglesey and other places belong here In the Devonian rocks of the Fichtelgebirge and Nassau picrites accompany dolerites and proterobasites as they do also in Cornwall and Devon The term picrite basalt is reserved for the poor basalts rich in olivine (C E T)

**PICROTOXIN**, a neutral principle obtained from the *Cocculus indicus* which is the fruit of the *Anamirta paniculata* It is used in medicine externally as an antiparasitic Internally it has been successfully used to check the night sweats of phthisis In large doses it is a powerful poison causing unconsciousness delirium convulsions gastroenteritis and stimulation of the respiratory centre followed by paralysis from which death sometimes results Formerly *Cocculus indicus* berries were sometime added to beer to increase the intoxicating effects The chemical formula of picrotoxin is  $\text{C}_{11}\text{H}_{16}\text{O}_6$

**PICTISH** The language of the ancient Picts is of uncertain origin and of doubtful affinity The Picts have left us a number of inscriptions in the Ogham character No attempt to interpret these inscriptions as any form of Celtic has produced anything but bosh Whatever may have been the Pictish language these inscriptions assure us that it was certainly not Celtic (R A Macalister in *Antiquity* II 7 1928 p 373) Examination of the symbols found upon monumental stones in Pictland suggest analogies with certain elements in Bronze age sculpturings—highly probable affinity if the Picts were the survivors of Bronze age aborigines influenced by La Tene culture

The term *Pict* itself may be connected with the Latin *Pictone* and *Pictari* of Gaul In Irish they are known as *Cruithne* in Welsh as *Prydyn* which (cf Prydem or British) significantly resembles the earliest Greek name for the British Isle *Pretonnec Island* From the matrilineal succession of their chiefs (the records being doubtful) it has been inferred that their social structure differed from that of other Gaelic speaking peoples Pictish extended to the north of Ireland and was finally ousted by the Gaelic speech of the Scots which was derived from Ireland

See T R Holmes *Caesar's Invasion of Britain* (1907)

**PICTOGRAPHY** In the history of writing a very large number of conventional marks are demonstrably reductions from still older forms which have often developed out of pictograph Pictography has left its traces in all parts of the world but was most widely developed in the New World as a system lasting down to modern times

Very simple pictures are drawn upon birch bark indicating by their order the subjects in a series of song chants with sufficient precision to enable the singer to recall the theme of each in his recitation An account can be kept of sales or purchases by representing in perpendicular strokes the number of items an adding at the end of each series a picture of the animal or object to which the particular series refers Thus three strokes followed by the picture of a deer indicate that the hunter has brought three deer for sale A conventional symbol (a circle with a line across it) is used to indicate a dollar a cross represents ten cents an upright stroke one cent so that the price can be quite clearly set forth This practice is followed in many other parts of the world In clay tablets discovered by Sir Arthur Evans at Knossos in Crete a somewhat similar method of enumeration is followed while at Athens conventional symbols were used to distinguish drachmae and obols upon the revenue records

In comparatively recent times the Dakota Indians invented a chronological table or winter count wherein each year is recorded by a picture of some important event which befell during the year In these pictures a considerable amount of symbolism was necessary A black upright stroke indicates that a Dakota Indian was killed a rough outline of the head and body spotted with blotches indicates that in the year thus indicated the tribe suffered from smallpox Sometimes in referring to persons the symbol of the nature of a rebus Thus Red Jacket an Indian chief was killed in the summer of 1808

with two arrows piercing it and blood dripping. There is however nothing of the nature of a play upon words intended. Here the Mexicans proceeded a stage further as in the often quoted case of the name of *Itz coatl* literally knife snake which is ordinarily represented by a reptile (*coatl*) with a number of knives (*itz*) projecting from its back. It is however also found divided into three words, *iz coatl*—knife pot water—and represented by a different picture accordingly. The Mexicans moreover to indicate that the picture was a proper name drew the upper part of the human figure below the symbol and joined them by a line a practice adopted also amongst their northern neighbours when as in names like *Little Ring*, the representation would hardly be sufficiently definite. Simple abstract notions could also be expressed in this picture writing. Salvation or famine was graphically represented by a human figure with the ribs showing prominently. A noose amongst the Mexicans was the symbol for robbery though more locally belonging to its punishment. In a Californian rock painting sorrow is represented by a figure from whose eyes drop tears. This could be abbreviated to an eye with tears falling from it a form recorded by Schoolcraft as existing amongst the Ojibwa Indians. The symbol is so obvious that it is found with the same value among Egyptian hieroglyphics.

To the more elaborate civilizations of the Old World the development of writing from pictography can be ascribed—the Assyrians (see *Cuneiform*) Egyptians (see *Egypt*) and Chinese (see *China*). Here more complex notions had to be expressed. The development of the system can be traced through many centuries and shows a tendency to conventionalize the pictorial symbols employed. Out of conventionalized forms develop (a) syllabaries (b) alphabets. As regards the latter the historical evolution is traced in the article *ALPHABET*. The account given under *CHINA (language)* gives a good idea of the development of a syllabary from pictographic writing.

**PICKTON, SIR THOMAS** (1758–1813) British general born at Poyston Pembrokeshire joined the army in 1775 as an ensign. On the disbandment of the 15th regiment in 1783 Pickton quelled a mutiny amongst the men by his prompt personal action and courage. After living in retirement on his father's estate for nearly twelve years he went out to the West Indies in 1794. He took part in the capture of St. Lucia (for which he was promoted lieutenant colonel) and in that of St. Vincent. After the reduction of Trinidad Abercromby made him governor of the island. He administered the island with such success that the inhabitants petitioned against the retrocession of the island to Spain. In October 1801 he was gazetted brigadier general. But by this time the rigour of his government as reported by his enemies had led to a demand by humanitarians at home for his removal. He was charged with permitting the application of torture under the Spanish law which he had to administer. Colonel William Fullarton (1754–1808) procured the appointment of a commission to govern the island with Pickton as its junior member. Pickton resigned and on his return to England in December 1803 he was arrested by order of the privy council. He was tried in the court of king's bench before Lord Ellenborough in 1806 on one of the charges on which the court returned a merely technical verdict of guilty which was superseded in 1808 by a special verdict on retrial. In 1810 at Wellington's request he was appointed to command a division in Spain. For the remaining years of the Peninsular War Pickton was one of Wellington's principal subordinates. The commander in chief it is true never reposed in him the confidence that he gave to Beresford, Hill and Craufurd but in the resolute thorough and punctual execution of a well defined task Pickton had no superior in the army. His debut was unfortunate. On the Coa in July 1810 Craufurd's division became involved in an action and Pickton his nearest neighbour refused to support him as Wellington's direct orders were to avoid an engagement. Details of the incident will be found in Oman *Peninsular War* vol. III. Shortly after this however at Busaco Pickton found and used his first great opportunity for distinction. He repulsed the French attack with skill and resolution. He fought at Fuentes d'Onor with Craufurd he stormed the breaches at Ciudad Rodrigo and in command of the

3rd division was at the storming of Badajoz. Wounds compelled a temporary absence in England but he again commanded the 3rd division at Vittoria in the battles of the Pyrenees and at Orthez and Toulouse.

On June 4 1814 Pickton received for the seventh time the thanks of the House of Commons for his great services and in 1815 he was made a G.C.B. Pickton was severely wounded at Quatre Bras but concealed his wound and retained command of his troops and at Waterloo two days later was shot through the head by a musket ball. His body was brought home to London and buried in the family vault at St. George's Hanover Square. A monument was erected to his memory in St. Paul's Cathedral.

See Robinson's *Life of Sir Thomas Pickton* (London 1836) with which however compare Napier's and Oman's histories of the Peninsular War as to controversial points.

**PICOU**, a seaport port of entry and capital of Picou county Nova Scotia 90 m N.E. by N of Halifax on a branch of the Canadian National railway. Pop. (1931) 315. It has several valuable industries and is the shipping port for the adjacent coal mines. The Academy was founded in 1818.

**PICTS**, an early people inhabiting Scotland of uncertain affinities probably pre-Celtic. They are first mentioned in A.D. 306. In 640 they defeated the Romans and harried the Roman Provinces (see *STRATHCLYDE*) until conquered in 846 by Kenneth (qv) MacAlpin. Tradition associates the Picts with the great stone monuments.

**PICUS** the Latin name of the woodpecker. This bird being sacred to Mars was widely revered in ancient Italy. Occasionally Picus is met with as a minor deity associated with Faunus as in the (late and artificial) legend of Picus Faunus and their capture by Numa Ovid *Fast.* iii 291 ff. Like many of the minor deities Picus was rationalized into an ancient king and a pedigree was made out as follows: Saturnus (qv) Picus Faunus (qv) Latinus (e.g. Virgil *Aen.* vii 45–49). Hence in various late accounts (a) as Saturnus was identified with Cronus Picus was made equivalent to Zeus see Halliday in *Class. Rev.* xxxvi p. 110 (1919). (b) For some unknown reason Varro (*ap. Augustine de cult. Dei* xviii 15) interpolated into the genealogy as father of Picus Stercutius (Sterces Sterculus the spirit of manuring fields). (c) Picus is confused with Picumnus a minor deity worshipped along with Pilumnus the spirit of the pestle (*pila*) (Nonius Marcellus p. 834 Lindsay citing Macer). (d) Ovid tells a romantic story to the effect that Picus loved a nymph Canens (the Singer) repulsed the advances of Circe (qv) and was turned by her into a woodpecker (*Met.* xiv 312 ff). This seems to be Ovid's own invention: most authors (as Virgil *Aen.* vii 189 Plutarch *quaest. Rom.* i) who tell the story of the metamorphosis say Circe was his wife.

See Carter in Roscher's *Lexikon* art. *Picus*.

**PIDDOCK**, a bivalve mollusc which bores into chalk cliffs below the low water line. Piddocks belong to the genus *Pholas* of the class *Lamelibranchia* (qv) and are remarkable in being phosphorescent (see *PHOSPHORESCENCE Animal*). The shell is curiously shaped in adaptation to their boring habit.

**PIDGIN ENGLISH**, the *lingua franca* of the seaports of China and the Straits Settlements a jargon mainly of corrupted English words following Chinese idiomatic usage. It is employed as a means of communication between foreigners and Chinese.

Pidgin is the Chinese corruption of *business*.

**PIECE OF EIGHT**, an obsolete Spanish coin properly the *pastre* or *peso* commonly also called a dollar, coined of silver and divided into eight *reals* whence piece of eight. Its value was four shillings. In 1797 when the Bank of England suspended payment millions of these coins were put into British circulation countermarked with a small oval bust of George III. The piece of eight was current in the Spanish American colonies.

**PIECE—WORK**, a term used to describe the method of industrial remuneration in which the worker is paid by the piece or job. In practice where piece work is arranged in trades that are organized the payment per unit of work is arranged by negotiation between the employers and employed as for example in the English cotton industry. Very often the agreements arrived at

are extremely complicated with various percentage variations upon a basic rate so that the expression of piece rate becomes very difficult for one outside the industry to understand. Agreements as to piece work are of an subject to a minimum wage arrangement. See WAGE SYSTEMS IN INDUSTRY.

**PIEDMONT** (pi ad mont) is a territorial division of north Italy, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine Graian Cottian Maritime and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria Cuneo Novara and Torino (Turin) to which Aosta and Vercelli were added in 1901. It has an area of 11,540 sq m. The people are chiefly engaged in agriculture—which is helped by irrigation. In 1901, the products were

	Area	Ton.
Wheat	85,000	46,800
Rye	124,000	6,080
Oats	41,000	2,040
Rice	109,400	6,580
Maize	37,250	97,100
French beans	87,000	18,600
Sugar beet	3,000	31,060
Hemp	7,100	2,700
Garden produce	10,500	58,600
Potatoes	5,500	11,500
Cocoons		6,000
Hay		668,100
Vines	703,750	6,516,000 (grapes)
		8,981,000 (wine—gallons)
Fruits (various)		114,170
Chestnuts	6,350	59,980

Many are also occupied in the reeling and throwing of silk and in the manufacture of cotton (no fewer than 50,000 workers of whom 37,000 are women) woollens and clothing there are also considerable manufactures at Turin Savigliano etc. The Piedmontese dialect has been rather strongly influenced by French. The total population of Piedmont was in 1901 3,407,493 in 1931 3,491,799. There are numerous summer resorts in the Alpine valleys. The chief railway centres are Turin communicating with the Mont Cenis line and with the Riviera by the railway over the Col di Tenda (in process of construction). The communications with Liguria are difficult owing to the approach of the mountains to the coast but the electrification of the lines from Genoa to Turin and Milan has greatly improved the travelling facilities of this region.

Piedmont (Ital. *Piemonte* Low Lat. *Pedemons* and *Pedemontium*) in Roman times until 49 B.C. formed a part of Gallia Transpadana and in Augustus's division of Italy formed with what was later known as Lombardy the 11th region. It formed part of the Lombard kingdom and it was not till about A.D. 1000 that the house of Savoy (*qv*) arose.

**PIEDMONT**, a residential city of California, U.S.A. on the heights adjoining Berkeley and Oakland. It has few shops and no factories and its building regulations prohibit the construction of multiple dwellings. The population was 9,533 in 1930 by the Federal census.

**THE PIEDMONT REGION** A term of special application in the U.S. to the low plateau which lies just east of the Appalachians especially in Pennsylvania, Virginia and the Carolinas.

**PIEDRAS NEGRAS**, formerly Ciudad Porfirio Diaz, a northern frontier town of Mexico in the State of Coahuila, 840 m N by W from Mexico City on the Rio Grande del Norte, 720 ft above sea level opposite the town of Eagle Pass, Texas. Pop. (1930) 15,878. An international bridge connects the two towns and the Mexican International railway has its northern terminus in Mexico at this point. The town has an important transfer trade with the United States and is the centre of a fertile district devoted to agriculture and stock raising. Coal is found in the vicinity. The Mexican Government maintains a custom house and military post here. The town was founded in 1849.

**PIENZA**, a town of Tuscany, Italy, in the province of Siena, 9 m west of the town of Montepulciano by road, 1,611 ft above sea level. Pop. (1931) 3,082 (town) 4,200 (commune). The

place was originally called Corsignano and owes its present name to Aeneas Silvius Piccolomini, Pope Pius II (*qv*) who was born here in 1405. The building which he caused to be erected by Bernardo Rossellino in 1460–1465 forms a noble group of early Renaissance architecture around the Piazza del Duomo. The latter retains Gothic details in the interior but the facade is simple Renaissance work. The other three sides are occupied by the episcopal and municipal palace and the Palazzo Piccolomini, the last resembling the Palazzo Rucellai at Florence. In the finest and is well furnished in front of it is a beautiful fountain and opposite it the fine Palazzo Armanniti. The canons' house contains a museum with some fine ecclesiastical vestments including an excellent 15th century cope of English origin and enamels.

**PIER**. In architecture (*qv*) it usually denotes a vertical support in masonry, brickwork or concrete which carries an arch or superstructure. In this sense it is applied both to those portions of a structure which are visible above ground and to isolated or detached supports underground described as foundation piers. The term is sometimes applied to the solid parts of a wall between windows or voids and also to the isolated masses of brickwork, masonry or concrete to which gates are hung.

**Bridge Piers**—In the construction of bridges (*qv*) and viaducts, a pier denotes the solid structure upon which the bridge superstructure (including arches) is supported. Occasionally in the case of high piers supporting viaducts and bridge superstructures the upper portions are constructed of open braced iron or steel work.

Foundation piers for bridges are formed of solid masonry, brickwork or concrete and sometimes reinforced concrete is employed for the purpose. In places where timber is abundant as in some parts of the United States and Canada, wooden cribs filled with rubble stone or concrete have been used for raising the foundations of piers out of water.

Special provisions must be made for the foundations of piers where the ground is soft for some depth or loose water-bearing strata are encountered and especially where the piers of large

THREE TYPES OF PIER USED IN ARCHITECTURE

bridges crossing rivers have to be constructed under water. Among the means employed in these situations are steel and iron cylinders, wells, caissons, bearing piles or some form of coffer dam within which the foundations may be constructed (See CAISSON FOUNDATIONS COFFER DAM).

Piles are sometimes employed to provide both the foundations and the piers carrying a structure of viaduct character. Thus screw piles having wide bearing blades of cast iron in the form of

a screw thread turned about a central shaft or column of cast iron or steel are sometimes sunk through soft strata till they reach a firm bed or one sufficiently consolidated by the superincumbent layers to enable it to support the weight imposed on the broad blades. Hollow cast iron cylindrical piles with a broad circular disc at the bottom to increase their bearing surface have also been used for piers founded in sand or soft strata of considerable thickness. They are sunk by hydraulic jetting, i.e. the scouring away of the soft material from under the disc by means of a jet of water emitted under high pressure from a pipe lowered within the pile. Water jets are also employed to facilitate the sinking of screw and other forms of piles. (See FOUNDATIONS.)

**Harbour Piers**—The term pier is often applied to works sheltering harbours such as the Tynemouth piers which are strictly breakwaters (*qv*). Landing stages also whether solid or open have for a long time been called piers as the Admiralty pier and the Prince of Wales pier at Dover the former essentially a breakwater with provision for berthing vessels and landing passengers on its sheltered side. The jetties (*qv*) thrown out from the shore to protect the entrance to a river harbour are also sometimes described as piers. In North America the term is commonly employed for a wharf structure that projects into a river fairway or harbour.

**Promenade Piers**—Open promenade piers form a common feature at seaside resorts. Promenade piers are usually supported on open pile work of timber cast iron or steel but in recent years reinforced concrete has been frequently employed both for the pile supports and superstructure. The open construction exposes little surface to waves or storms and does not interfere with the drift of shingle and sand along the coast. It is essential that the beams or girders carrying the deck of a promenade pier should be at an elevation well above the level of the crest of the highest wave. Timber piles are best suited for withstanding the shocks of vessels at landing stages at which places they are generally used. In the case of reinforced concrete landing stages a falsework of timber is sometimes constructed in front of the main structure for this purpose. Screw piles are frequently used for promenade piers on sandy foreshores.

The pioneer of promenade piers in England was the old chain pier at Brighton erected in 1822-3. It was founded on oak piles was 1136 ft long and was destroyed by a gale in Dec. 1896. The length of promenade piers depends mainly on the distance from the shore at which sufficient depth is reached for steamers. Thus piers at Southend (Essex) and Southport (Lancs.) have been constructed across the wide sands in the estuaries of the Thames and Ribble respectively the former over 1½ m. the latter nearly a mile in length.

Works on bridge and other foundations are noted at the end of the article CAISSON. (N. G. G.)

**In Architecture**—A pier in architecture is a vertical support carrying arches a vault a floor or a roof especially one rectangular in plan also in mediæval work any support between the nave and aisles of a church. During the late Roman imperial period pier design was carefully studied and in connection with such buildings as the basilicas cross shaped and other compound piers were developed to carry the cross arches and the groins or intersections of the vaulting. With the increasing use of vaulting for church naves and aisles during the 11th and 12th centuries pier design was still further developed. Although in England Norman piers are frequently great round columns on the continent of Europe piers became common in which each arch or vaulting rib above was carried by a separate member of the pier. The earliest logical expression of this idea is found in Italian Lombard work where a square pier has frequently an engaged column attached to each face the one on the nave side carrying the cross rib of the nave vault that on the aisle side carrying the aisle vault cross rib and those on the other two sides carrying the pier arches between nave and aisles.

During the later Romanesque pier plans were further complicated by the addition of smaller members to carry the subsidiary mouldings of the arches above, and larger members to carry the diagonal vaulting ribs. (See BYZANTINE AND ROMANESQUE ARCHITECTURE.)

During the 13th and 14th centuries the piers of French Gothic churches were kept comparatively simple in plan with great importance given to the capital at the level of the spring of the pier arch. Often it took the shape of a circular column with a few large simple attached vaulting shafts as in Rheims cathedral (c. 140). Toward the end of the 14th century perhaps due to English influence the column idea disappeared and was replaced by the more logical plan in which the pier was elaborately membered not only by the additional development of vaulting shafts but by breaking up the edges with projecting mouldings under the mouldings of the arches. Capitals became of less importance and vaulting shafts were carried unbroken through from floor to vault spring capital being placed merely on the separate moulding of each arch or rib.

During the Flamboyant period this development was carried to its logical extreme capitals were omitted entirely and the pier plan became the combination of the various arch and vault rib mouldings continued down to the floor. Against this complexity a reaction was inevitable and the other type of French Flamboyant pier developed with smooth surface either circular or wavy in plan with the various vault rib and arch mouldings carried by the pier merely dying into it at their intersections. In England during the Early English period although circular piers are occasionally found they were more frequently surrounded by entirely independent colonnettes often of black Purbeck marble which act as vaulting shafts and are tied to the body of the pier only at intervals by horizontal through stones with moulded edges. During the Decorated period attached shafts continued in use but the surfaces of the central core appearing between them were often richly moulded and in some cases detached shafts disappeared entirely and the pier became a solid mass with surfaces lavishly moulded with strong projecting high lights and deeply cut shadows.

In the late Decorated period mouldings of the pier were sometimes the same as those of the arch above and capitals were omitted. This arrangement became much more frequent during the Perpendicular period. Pier moulding profiles were softened and flattened like other mouldings of the period. (See GOTHIC ARCHITECTURE.) With the coming of the Renaissance pier design was much simplified returning to the generally cross shaped or twelve cornered systems found in late Roman work with all the projecting members treated either as classic impost engaged columns or pilasters.

Technically the word pier is also applied to the solid portion of a wall between windows or other openings and to the vertical posts at gateways to which the gates are hung. The word pier is used of structures of timber or masonry projecting from quay or sea wall and used either for loading and unloading ships or in the case of summer resorts for furnishing promenade space into the water. In America the word is loosely used synonymously with dock or landing stage.

**PIERCE, FRANKLIN** (1804-1869) fourteenth president of the United States was born at Hillsboro New Hampshire Nov. 3 1804. His father Benjamin Pierce (1757-1839) served in the American army throughout the Revolutionary War was Democratic member of the New Hampshire house of representatives from 1789 to 1801 and was governor of the State in 1827. The son was prepared for college at Hancock Francetown and Exeter academies and entered Bowdoin in 1820 where he formed a lifelong friendship with Nathaniel Hawthorne. After his graduation in 1824 he studied law and was admitted to the bar in 1827.

**Entry into Politics**—Entering politics as a Democrat he became a member of the New Hampshire house of representatives in 1829 and was speaker of that body in 1831 and 1832. The following year he entered the national house of representatives. While he rarely spoke from the floor he was an influential member of several committees including the judiciary committee. A friend of President Jackson he supported administration policies. He adhered to a strict construction of the Federal Constitution defended the Maysville veto opposed the recharter of the bank of the United States opposed appropriations to the U. S. military academy and favoured a volunteer army. During

his first term in Congress he married Jane Means Appleton daughter of the president of Bowdoin college. In 1833 he entered the U S Senate. Being its youngest member he was overshadowed by a galaxy of older and more prominent men such as Benton Clay and Webster. Before his term expired he resigned his seat (1840) and returned to the practice of law at Concord N H where he became Federal district attorney. In 1843 he was offered the Democratic nomination for governor of New Hampshire as an appointment to fill an unexpired term in the U S Senate and the next year the position of attorney general in Polk's cabinet but he rejected them all declaring that he had permanently retired from political life.

**Service in Mexican War**—Shortly after the outbreak of the war with Mexico in 1846 Pierce enlisted as a private at Concord but soon became colonel of the 9th Regiment and later a brigadier general of volunteers. He was with Gen Scott in the advance toward Mexico City. During the battle of Contreras he was thrown from his horse and received painful injuries. Despite the advice of Scott to the contrary he insisted on continuing the fight the next day and in the course of the battle he fainted. This fact variously interpreted was used both for and against him when he was later a candidate for the presidency. At the close of the war he returned to his law practice.

**Election to Presidency**—Pierce became the Democratic nominee for president in 1853 as a dark horse. Those in the foreground were Lewis Cass, Stephen A. Douglas and James Buchanan but none of these proved to be available because of factional rivalries. A few politicians foreseeing a deadlock had prepared Pierce for the place. At the convention in Baltimore in June his name was first brought forward by the Virginia delegation on the 35th ballot and on the 49th ballot he received an almost unanimous vote. Both the Democrats and the Whigs were too badly split for any real issues to appear in the campaign. The chief question in the public mind was the finality of the Compromise of 1850 and while both parties declared themselves in favour of it the Democrats were more thoroughly united in its support. As a result Pierce swept the country in the November election receiving 254 electoral votes against 42 for his opponent Gen Winfield Scott.

**Presidential Administration**—The youngest man to have been elevated to the presidency Pierce was handsome genial and possessed of a certain brilliance which however was not profound. The Eastern element of the Democratic party which he directly represented was inclined for the sake of harmony and prosperity to oppose anti-slavery agitation and generally to placate Southern opinion. It was hence pro-Southern as a matter not only of political strategy but also of business expediency. Thus in the selection of his cabinet as in both domestic and foreign policies of his administration Pierce represented a coalition of Southern planters and Eastern business men. His cabinet included William L. Marcy of New York secretary of state, Jefferson Davis of Mississippi secretary of war, James Guthrie of Kentucky secretary of the treasury, James C. Dobbin of North Carolina secretary of the navy, Robert McClelland of Michigan secretary of the interior, James Campbell of Pennsylvania postmaster general and Caleb Cushing of Massachusetts attorney general. In his inaugural address Pierce interpreted his election as a popular mandate to maintain the Compromise of 1850 and bury the slavery controversy. He also forecast an aggressive but honourable foreign policy; he would not be controlled by any timid forebodings of evil from expansion. In fact the acquisition of certain possessions (doubtless referring to Cuba in particular) was deemed essential to the country's safety and commerce.

**Foreign Policy**—In accordance with the declarations of the inaugural Pierre Soule who had openly advocated the annexation of Cuba by means other than purchase if necessary was appointed minister to Spain. When the Spanish Government showed its unwillingness to sell the island Soule at the suggestion of secretary of State Marcy held a conference with James Buchanan minister to Great Britain and John Y. Mason minister to France at Ostend Belgium as a result of which they issued the famous Ostend Manifesto. This was to the effect that if the

United States were unable to obtain Cuba peacefully by every law human and divine we shall be justified in wresting it from Spain if we possess the power. In the form of controversy which followed the administration claimed responsibility for the document and recalled Soule. The following year William Walker conducted a notorious filibustering expedition into Central America with the purpose of establishing a pro-slavery government to be brought under the control of the United States. He established himself a military dictator then as president of Nicaragua and his regime was recognized by the Pierce administration. More fruitful of permanent result was the expedition sent out under Commodore Perry to Japan (1853) to induce her to open her door to American trade. Lured by Yankee ingenuity and frightened by Western guns she responded and the result was the opening up of Japan. In the Koszta affair (1853) the government vigorously asserted the protection which it would offer those in the process of becoming its naturalized citizens. The administration also effected a reorganization of the diplomatic and consular service and the creation of the U S court of claims.

**Domestic Policy**—Among the domestic policies of the Pierce administration were preparations for a transcontinental railroad and the opening up of the Northwest for settlement. It was in order to open the way for a southerly route to California through the lowest mountain passes that the Gadsden Purchase of 50 000 sqm of territory was acquired from Mexico in 1853 at a cost of \$10 000 000. It was mainly to stimulate migration to the Northwest and facilitate the project of a central route to the Pacific that the Kansas-Nebraska bill was enacted in 1854 receiving the President's sanction. This opened two new territories for settlement with the slavery question to be settled in each by popular sovereignty. Thus the dread conflict was reawakened with the venom of incipient civil war. Pierce's administrative policies with reference to bleeding Kansas were pro-Southern. He thus lost much of his former support at the North and made himself unavailable as a candidate for a second term.

Save for a three years tour in Europe he lived at Concord N H where he died on Oct 8 1869.

**PIERO DI COSIMO** (1462-1511) the name by which the Florentine painter Pietro di Lorenzo is generally known. He was born in Florence in 1462 and worked in the *bottega* of Cosimo Rosselli (from whom he derived his popular name). He had the gift of a fertile fantastic imagination which as a result of his journey to Rome in 1482 with Rosselli became directed towards the myths of classic antiquity. In Rome he assisted his master with the frescoes in the Sistine chapel. He proves himself a true child of the Renaissance in such pictures as the Death of Procris at the National Gallery the Mars and Venus at the Berlin Gallery the Perseus and Andromeda series at the Uffizi in Florence and the Hylas and the Nymphs of the late Benson collection. The Immaculate Conception at the Uffizi and the Holy Family at Dresden are good examples of his religious pictures. Piero was distinguished for his landscapes and their cheerful accessories. The only known portraits that can be definitely ascribed to him are at the National Gallery the so called Bella Simonetta at Chantilly the portraits of Giuliano di San Gallo and his father at The Hague and a head of a youth at Dulwich. Vasari related that Piero excelled in designing pageants and triumphal processions for the pleasure-loving youths of Florence. Piero di Cosimo exercised considerable influence upon his fellow pupils Albertinelli and Bartolommeo della Porta and was the master of Andrea del Sarto. Examples of his work are also to be found at the Louvre in Paris the Liechtenstein collec-

tion in Vienna the Borghese and Corini Galleries in Rome the Berlin Museum the Spedale degli Innocenti in Florence and in the collection of Burke in London and Cornwallis West in Newlands Manor

**PIERRE**, the capital city of South Dakota U.S.A. and the county seat of Hughe county in the centre of the State on the east bank of the Missouri river opposite the mouth of Bad river at an altitude (at the State capitol) of 1496 ft. It is on Federal highways 14 and 83 has a municipal airport and is served by the Chicago and Northern Western railway. Pop. 1930 Federal census 3659. Four miles north of the city is a monument marking the geographical centre of the State and the approximate centre of North America. The State capitol (erected 1903-10) is a beautiful building 9 ft long by 14 ft wide and 161 ft high to the top of the lantern. Near the capitol is an artificial lake fed from an artesian well by water which never freezes where swans, geese and wild ducks live the year round. The city owns more than a mile of river frontage and its parks include a wooded island of 1000 acres. Artesian wells supply the city not only with water but also with natural gas of high heating content. Pierre is the seat of a government Indian school and of Northern college (Christian, established 1901). The State Historical Museum (in the capitol) has many interesting relics including a leaden plate buried in 1743 by La Verendrye on a hill across the river (within the present city of Fort Pierre) to claim the country for France and discovered by high school children in 1913. Pierre is an important shipping point and centre of wholesale and jobbing interests. It has railroad shops, granite works and other manufacturing industries. The first permanent settlement by white men in South Dakota was made in 1817 by Joseph La Framboise a fur trader just below the mouth of Bad river. He called his post Ft. Teton. In 1827 Ft. Tecumseh was built 100 m up stream and in 1837 when its site was washed into the river Ft. Pierre Chouteau was erected to take its place a mile farther up stream and a little back from the river. It was named after Pierre Chouteau Jr. (1789-1865) who had in 1804 succeeded his father in the Missouri Fur Company and for 10 years Ft. Pierre (as it soon came to be called) was the chief fur trading depot of the Upper Missouri country. In 1855 the United States bought the building and other property of the post and laid out around them a military reservation of 200 sq m (abandoned in 1857) which was the headquarters of operations against the Sioux and the scene of a council with their chiefs. In the early days steamboats plied regularly on the Missouri river as far as Ft. Benton (Montana) 1000 m above Pierre. The first sermon in South Dakota was preached in 1840 by the Rev. Stephen R. Riggs a missionary to the Dakota Indians on a spot near the free wagon bridge across the Missouri which bears his name. The city was platted in 1880 incorporated as a village in 1883 and chartered as a city in 1900. One of the few surviving herds of buffalo in the United States is quartered in the river brakes 4 m north of Fort Pierre.

**PIERREFONDS** a town of northern France in the department of Oise 9 m S.E. of Compiègne by road. Pop. (1931) 1001. Pierrefonds has an 11th to 16th century church and its mineral springs are in some repute. The famous chateau was begun in the late 14th century by Louis d'Orleans to whom the domain was given by Charles VI and finished early in the 15th century. It was later held by the Burgundians, the English and the adherents of the League from whom it passed to Henry IV. It was dismantled in 1627. The ruins bought by Napoleon I were faithfully restored by order of Napoleon III in 1858-95 under the direction first of Viollet le Duc and afterwards of E. Boeswillwald. The building is rectangular in shape with a tower at each corner and at the centre of each of the walls. A lofty keep defends the principal entrances on the south west.

**PIERROT** [Ital. *Pedrolino*] the name given to the leading character in the French pantomime plays since the 18th century transferred from the Italian stage and revived especially in recent times. He is always in white both face and costume with a loose and daintily clownish garb and is represented as of a

freakish disposition. Modern pierrot plays have converted the pierrot into a romantic and pathetic figure. (See PANTOMIME.)

**PIETAS**, in Roman mythology the personification of the sense of duty towards God and man and towards the fatherland. According to legend a young woman in humble circumstances whose father (or mother) was lying in prison under sentence of death without food managed to gain admittance and fed her parent with milk from her breast. To commemorate her filial affection a temple was dedicated (181 B.C.) by Manius Acilius Glabrio to Pietas in the Forum Holitorium at Rome on the spot where the young woman had formerly lived. The temple was probably originally vowed by the elder Glabrio out of gratitude for the *pietas* shown during the engagement by his son who may have saved his life as did the elder Africanus that of his father at the battle of Ticinus (Livy xxi 46) the legend of the young woman (borrowed from the Greek story of Mycon and Pero Val. Max v 4 ext 1) was then connected with the temple by the identification of its site with that of the prison. Pietas is shown on coins as a matron throwing incense on an altar her attribute being a stork. Typical examples of piety are Aeneas and Antoninus Pius who founded games at Puteoli in honour of Hadrian.

**BIBLIOGRAPHY**—See Val. Max v 4 7. *Phryn. Nat. hist.* vii 121. Livy xl 34. Festus s.v. *G. Wisowa, Religion und Kultus der Römer* (1900). F. Kuntze *Die Legende von der guten Tochter* in *Jahrbücher für das klassische Altertum* (1904) viii 280.

**PIETERMARITZBURG**, the capital of Natal South Africa 29° 46' S 30° 13' E altitude 18 feet. Though only 41 m inland it is 15 m by rail from the port of Durban. The main town is laid out on a low ridge between the Umsundusi River and the Dorp Spruit. Suburbs have grown up on two other ridges across the river to the south east of the town and also on the slopes of a marked escarpment which rises over 1500 ft above the town on the north west side. The low ground between the ridges is occupied either by Indian dwellings and cultivation or by open spaces laid out as public parks and sports grounds with which the city is very well provided. On the west of the town are the botanical gardens. There are memorials of the Zulu, South African and World Wars. The town was founded in 1839 by Dutch immigrants and connected by railway with Durban in 1880.

Among the public buildings are the town hall containing a remarkably fine organ and a good collection of pictures, the Provincial Council building, the Colonial offices, the Court house, the post office and the museum which has an exceedingly good collection of the South African fauna. The Voortrekkers museum is housed in what used to be a Dutch church. The Natal Society library is also admirable. The city is the seat of an Anglican bishop. It is noted for its agricultural show held every June. There is a large number of high schools for day pupils and boarders both in the city and outside. In addition there is a training college and a university college a constituent of the University of South Africa. Means of locomotion are provided by a tramway system, jirikshas and motor cars. In 1911 the population included 9992 natives, 6944 Asiatics, 1089 coloured people and 17998 Europeans. The latter had increased by 1931 to 20944.

**PIETERSBURG**, chief town of the Pietersburg district of the Transvaal 177 m by rail N.N.E. of Pretoria altitude 4269 ft. Pop. (1921) 245 whites, 3325 natives, 183 Asiatics and 103 coloured, total 6063. The surrounding country contains minerals. To the east are the Klein Letaba and other low country goldfields, to the west are the Waterberg goldfields. Asbestos, tin and corundum also occur, the latter being exported in fair quantity. Cereals, tobacco, cotton and groundnuts are cultivated and towards the east citrus estates have developed.

**PIETERS HILL**, 10 miles S.S.E. of Ladysmith has given its name to the fourth and finally successful British attempt to relieve Ladysmith at the end of Feb. 1900 (see LADYSMITH and SOUTH AFRICAN WAR). Buller having tried a frontal attack and two attacks on the right of the Boer lines, now resolved to assail their left and the operations opened with the successful storming of their positions on the south bank of the Tugela east of Colenso which fell into British hands after six days of methodical

fighting Thereafter Buller drew back the bulk of his force to the north bank its next objective being the group of hills immediately north of Colenso On Feb , the British right wing captured Pieters Hill the northern buttress of the ridge and next day Buller's cavalry entered Ladysmith which had stood a four months siege

**PIETISM** a movement in the Lutheran Church which arose towards the end of the 17th and continued during the first half of the following century The name of Pietists was given to the adherents of the movement as a term of ridicule like that of Methodists somewhat later in England The Lutheran Church had continued Melancthon's attempt to construct the evangelical faith as a doctrinal system and it appeared to many faithful adherents to have become a creed bound theological and sacramentarian institution where the dogmatic formularies of the Church had usurped the position which Luther himself had assigned to the Bible alone The influence of the Reformed Church (qv) on the other hand in spite of the predestinarianism of Calvin made less for doctrine than the practical formation of Christian life The Presbyterian constitution gave the people a share in church life which the Lutherans lacked but it involved a dogmatic legalism which imperilled Christian freedom and fostered self righteousness

The direct originator of the movement for the revival of a practical and devout Christianity was Philip Jacob Spener who combined the Lutheran emphasis on Biblical doctrine with the Reformed tendency to vigorous Christian life Born at Rappoltsweiler in Alsace on the 13th of January 1635 trained by a devout godmother who used books of devotion like Arndt's *True Christianity* accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds Spener was early convinced of the necessity of a moral and religious reformation of the German Church He studied theology with a view to the Christian ministry at Strassburg and entered upon his first pastoral charge at Frankfurt on the Main profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy Pietism as a distinct movement in the German Church was then originated by Spener by religious meetings at his house (*collegia pietatis*) at which he repeated his sermons expounded passages of the New Testament and induced those present to join in conversation on religious questions that arose They gave rise to the name Pietists In 1675 Spener published his *Pia desideria* or *Earnest Desires for a Reform of the True Evangelical Church* In this publication he made six proposals as the best means of restoring the life of the Church (1) the earnest and thorough study of the Bible in private meetings *ecclesiolae in ecclesia* (2) the Christian priesthood being universal the laity should share in the spiritual government of the Church (3) a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement (4) instead of merely didactic and often bitter attacks on the heterodox and unbelievers a sympathetic and kindly treatment of them (5) a reorganization of the theological training of the universities giving more prominence to the devotional life and (6) a different style of preaching namely in the place of pleasing rhetoric the implanting of Christianity in the inner or new man the soul of which is faith and its effects the fruits of life This work produced a great impression throughout Germany and although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by Spener's book its complaints and its demands were both too well justified to admit of their being point blank denied A large number of pastors at once practically adopted Spener's proposals In Paul Gerhardt the movement found a singer whose hymns are genuine folk poetry In 1686 Spener accepted an appointment to the court chaplaincy at Dresden which opened to him a wider though more difficult sphere of labour One of his most enthusiastic disciples was August Hermann Francke who had founded the famous orphanage at Halle and with the aid of Christian Thomasius and Spener founded the new university there The theological chairs were filled in conformity with Spener's proposals Spener died in 1705 but the movement guided by Francke spread over Middle and North Germany One

of its greatest achievements was the organization of the Moravian Church in 1727 by Count von Zinzendorf Spener's godson and a pupil in the Halle Orphanage

Pietism of course had its weaknesses Many Pietist maintained that the new birth must always be preceded by agonies of repentance and that only a regenerated theologian could teach theology while the whole school shunned all common worldly amusements such as dancing the theatre and public games There thus arose a new form of justification by works

A distinct movement Pietism had run its course before the middle of the 18th century by its very individualism it had helped to prepare the way for another great movement the Illumination (*Aufklärung*)

**PIETRO DELLA VIGNA** or **PIER DELLE VIGNE** [PETRUS DE VINEAS or DE VINIS] (c 1190-1149) chancellor and secretary to the emperor Frederick II born at Capua in humble circumstances studied law at Padua He became secretary to Frederick II who made him *iudex magnae curiae* councillor governor of Apulia protonotary and chancellor The emperor of whose heart he held the keys as Dante says sent him to Rome in 1232 and 1237 to negotiate with the pope to Padua in 1239 to induce the citizens to accept imperial protection to England in 1243-45 to arrange a marriage between Frederick and Isabella sister of King Henry III He proved a skilful and trustworthy diplomat and he persistently defended the emperor against his traducers and against the pope's menaces At the Council of Lyons Pietro della Vigna entrusted the defence of his master to the jurist Taddeo of Suessa who failed to prevent his condemnation Frederick had his chancellor imprisoned and blinded without giving him a chance to rebut his accuser He is said to have committed suicide in his prison at Pisa in 1149 His tragic fate gave rise to many legends

Pietro della Vigna wrote verse in the vernacular tongue of which two *canzoni* and a sonnet are extant His letters (*Epistolarum libri vi* 2 vols Basel 140) are of historical value A collection of the laws of Sicily a *Tractatus de potestate imperiali* and another treatise On Consolation in the style of Boethius are also attributed to him

**PIG** (a word of obscure origin connected with the Low German and Dutch word of the same meaning *bigge*) a common name given to the domestic swine (For the zoology see **SWINE**)

**British Breeds**—Twelve breeds are recognised in Britain—

The *Large White* or large Yorkshire is a breed which has been evolved in the north of England and is now very wide spread and important The animals are large long and deep and when young even if heavily fed do not readily become too fat The head is long light in the jaw and wide between the eyes with long thin ear inclined slightly forward and fringed with long fine hair The neck is long but not coarse the ribs are deep the loin wide and level the tail set high and the legs straight and set well outside the carcass The whole body including the back of the neck is covered with straight silky hair which denotes quality and lean meat Pigs of this breed are very prolific and they may be grown to enormous weights—over 11 cwt alive

The *Middle White* is considered to have been produced by crossing the Large White and the now extinct Small White The latter was a small early maturing and excessively fat type of pig The Middle Whites are built on a smaller scale than the Large Whites They are shorter in the heads and legs and fuller at the jaw thicker and more compact in the body The sows are not quite as prolific as those of the Large White breed but as their

produce matures earlier they are much in demand for breeding porkers. If fed to heavy weights the animals become too fat.

The *Lincolnshire Curly Coated* or *Boston* pig is a local breed of great size and capacity for producing pork. It is very hardy and prolific but somewhat coarse in the bone. It has an abundance of long curly hair, a short face and a straight nose and the ears not too long and heavy fall over the face. It crosses well with the *Large White*, the *Large Black* and the *Berkshire*.

The *Large Black* breed which vies with the *Large White* breed for size has only since 1900 received national show yard recognition but there is ample evidence that with its characteristic whole black colour with a mealy hue, length, fine hair and lop ear the *Large Black* existed in the south of England for generations. It has been continuously and carefully bred in Cornwall, Devon, Essex and Suffolk and from these centres it has rapidly spread all over the country. *Large Blacks* are exceedingly docile and the ears hanging well forward over the eyes contribute materially to a quietness of habit which renders them peculiarly adapted to field grazing. On account of their hardiness and disposition to early maturity they have proved valuable for crossing. The *Large Black Pig Society* was incorporated in 1899.

The *Berkshire* is a black pig with a pinkish skin and a little white on the face, pasterns and tip of the tail. It has a moderately short head with a deep compact carcass and wide low and well developed hind quarters with heavy hams. The skin carries an abundance of fine hair. The *Berkshire* is an early maturity breed which has been somewhat inbred and is not so hardy and prolific as most breeds. The boars cross well with common stock. The breed produces meat of outstanding quality and is extremely difficult to beat in carcass competitions; it does best when fed for the pork market.

The *Tamworth* is one of the oldest breeds of pigs and is considered to be directly descended from the wild native pig. The colour is red or chestnut. The head, body and legs are long and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred and highly valued as a bacon pig.

The *Cumberland* is a pig of the *Large White* type. It is however shorter and thicker in form; it has a dished face and drooping ears. The hair is fine and sparse. The breed fattens readily and the pork is of good quality.

The *Long White Lop Eared* was formed by amalgamating the Old Glamorgan and Welsh breeds which were of a similar type. The general conformation is very similar to that of the *Large Black*. The animals are hardy and they do well in the open air.

The *Large White Ulster* is of the *Large White* type but compared with that breed it is shorter in the body, finer in the hair, thinner in the skin and possesses drooping ears. It is very suitable for the bacon trade and is kept in Ulster practically to the exclusion of all other breeds.

The *Gloucestershire Old Spots* is an old local type which was constituted as a pure breed in 1914. The breed is rather thicker in form than is the *Large White*. The colour is black and white in fairly large clearly defined spots. The head is of medium length, the ears are long and drooping. The animals are hardy and they are very suitable for the heavy pork trade.

The *Wessex Saddleback* and the *Essex* are two breeds of very similar conformation and colour markings. The colour is black with a white saddle and white fore legs. The *Essex* also has white on the hind legs, the tail and the nose. The animals are of medium size and are considered to be hardy.

**Management**—The brood sow should be lengthy and of a prolific strain known to milk well. She is moderately fed and put to a boar of her own age when large enough, i.e. seven to eight months old. She remains in a state of oestrus for about three days and if not pregnant comes in heat again in three weeks. Breeding swine, male and female, run most of their time at pasture and receive a liberal allowance of green food or raw roots. The period of gestation is sixteen weeks. Six to eight pigs are reared of the first litter and ten to twelve afterwards. Many brood sows are fattened to greatest profit after the second or third litter but on the other hand the animals may be kept as

long as they are satisfactory breeders. Two litters are produced in one year as pigs are usually weaned at two months old and the sow will take the boar at from three days to a week after the pigs are removed according to condition.

The digestive system of the pig is not fitted to deal with fibrous or bulky toddlers and the food should be highly concentrated. In practice pigs are fed largely on dairy by products such as whey and separated milk, milling offals, cereal meals, waste potatoes and kitchen scraps. Pigs do well on mixtures of milk products and cereal meals or offals. If no milk or whey is available the meals or potatoes should be balanced with 10% of white fish meal or meat meal or other foodstuff rich in albuminoids. Kitchen scraps should be cooked and the fat skimmed off before being given to pigs. Potatoes are best fed in a cooked condition. Chalk and other mineral matter are often added.

Every endeavour should be made to provide young pigs with some milk or milk product for a time after weaning. Fattening pigs should be given from  $\frac{1}{2}$  to  $\frac{1}{4}$  lb of mixed cereal meals or their equivalent of other foods for every week of age. Thus at 1 week the pig should get about  $2\frac{1}{2}$  lb of dry meal or its equivalent per day; at 10 weeks about  $4\frac{1}{4}$  lb; at 30 weeks about  $\frac{1}{2}$  lb. Another rough rule is to give 1 lb of meal for every 25 lb live weight. With dry food water will of course have to be available. Sows in pig require about 5 lb of meal or its equivalent per day; sows in milk need 10 or 12 lb. It is usual to spread the ration over three meals per day.

Porker pigs are frequently slaughtered when about  $4\frac{1}{2}$  months old and 100 lb live weight; they yield about 65 lb of dressed carcass. Many pigs are however marketed for pork at much greater weights. A typical bacon pig should weigh about 220 lb live weight or 165 lb carcass weight and should be ready for slaughter when 7-8 months old.

**BIBLIOGRAPHY**—R. Wallace *Farm Live Stock of Great Britain* (1923); C. S. Plumb *Types and Breeds of Farm Animals*; Watson and More *Agriculture: The Science and Practice of British Farming* (1928); Henry and Morrison *Feeds and Feeding*. Also *The Herd Books of the Breed Societies* and official publications of the Agricultural Departments of Great Britain, Canada and the United States (R. W. J. A. Mo).

**The United States**—The *Poland China* breed originated in Ohio principally in the counties of Butler and Warren. The foundation stock consisted of so-called Bedford, Woburn, Russian and Irish Grazier hogs improved by an introduction of *Berkshire* blood. The breed was at first white and black spotted but later the black body with white at the face, feet and tip of tail became the standard colour. The breed is large in size; boars commonly weighing 1,000 lb while sows at maturity often weigh as high as 800 lb. Lengthy proportions combined with height, ruggedness of bone and meat producing qualities are especially stressed in this breed. The head of the *Poland China* is rugged in appearance, medium in length and slightly dished in the profile. The ear is rigid from the point of attachment on the head to approximately one half to two thirds of its length with the tip one half or one third broken over. In body conformation the *Poland China* is long, deep and tall. The shoulders are smooth and compact and the back is evenly and smoothly arched. This breed is found in all parts of the United States as well as in many other countries.

The *Duroc Jersey* originated in the eastern part of the United States mainly in New York and New Jersey. The foundation stock it is thought came from Africa, Portugal and Spain. In general the conformation of the *Duroc Jersey* resembles that of the *Poland China*. However the head is smaller and more refined and the back is somewhat more evenly arched. In colour this breed ranges from a light golden yellow to what approximates a mahogany brown. The ideal colour, however, is a deep golden yellow inclining to a cherry red.

The *Chester White* originated in Chester county, Pa. The foundation stock consisted of native stock combined with English hogs, particularly the *Large Yorkshire*. Individual breeders have at various times attempted to establish other breeds similar in character and breeding to the *Chester White*. A notable example of this is the so-called O.I.C., which means the Ohio Improved

**Chester White** This latter so called breed is organized into a breed association and the breeders record their animals separately from the Chester White. There seem to be little to distinguish one breed from the other. The Chester White is pure white in colour although black or bluish spots known as freckles are frequently found on the hide. In size the Chester White does not quite rank with the Poland China or the Duroc Jersey. Boars at maturity however often weigh 900 lb. while the females commonly reach a weight of 600 lb. A medium sized head and ear clean trim jowls and an evenly turned back are characteristic of the Chester White. Like the Poland China and Duroc Jersey one half to one third of the tip end of the ear is broken over. This breed is quite popular in the corn belt but due to its white colour does not stand the sun as well as a dark coloured breed.

The **Hampshire** breed while a native of America originated from English stock probably the Wessex Saddle Back and the Essex. In colour markings the American Hampshire resembles these breeds. The Hampshire has had its greatest improvement in Ohio Illinois Iowa and other corn belt States. The breed has gained its popularity through its fecundity foraging properties and its ability to yield a high grade carcass. Among the common lard breeds in America the Hampshire is relatively small. It is extremely trim in its lines is especially clean cut about its head and is smooth and firm in its bone. The face of the Hampshire is straight in profile and the ears are rigid from point of attachment at the head to the tip end. The promoters of this breed discriminate against heavy jowls dished faces and any tendency toward roughness.

The **Berkshire** breed is a native of England but has received considerable attention in America. It is classed as a lard breed and has been especially noteworthy because of the high quality of carcass it produces. The Berkshire has the same colour marking as the Poland China but is not so large in size. The ears are rigid and the face is dished.

The **Tamworth** and **Large Yorkshire** are the two most common bacon breeds in America. Both these breeds received their origin in England and are similar in body conformation. They differ however in colour. The Large Yorkshire is white while the Tamworth is red similar to the Duroc Jersey in this respect. The bacon breeds are less popular than lard breeds. (J S C)

**PIGEON**, a name of Norman introduction for certain birds of the family Columbæ (see Dove). Perhaps the best known species to which the name is exclusively applied is the passenger pigeon (*Ectopistes migrarius*) of North America. Formerly nesting in countless multitudes in the then backwoods of Kentucky Ohio and Indiana this bird is now extinct the last specimen dying in Cincinnati Zoological Gardens in 1914. The passenger pigeon was about the size of a turtle dove but with a long wedge shaped tail. The male was a dark slate colour above and purplish bay below the female drab above dull white beneath. The beautiful fruit pigeons (*Treron*) of tropical Africa India and the Malay Archipelago are perhaps the most delicately flavoured of all birds.

The largest forms are the giant crowned pigeons (*Goura*) of New Guinea. They have a beautiful filmy fan shaped crest on the head. The Nicobar pigeon (*Caloenas*) is remarkable for the long lustrous neck hackles and its peculiar gizzard.

Pigeons lay two or three white eggs and the naked helpless young are fed by a secretion from their parents' crops (pigeon milk).

**PIGEON FLYING**, the sport of racing homing pigeons bred and trained for the purpose. It is of very recent date although the use of birds as a means of carrying messages (see PIGEON POST) is of great antiquity. Belgium may be considered as *par excellence* the home of the sport the first birds flown there probably coming from Holland. Long distance flying began in 1818 with a match of 1000 miles while in 1820 there was a race from Paris to Liege, and in 1823 from London to Belgium. The Belgian *concours national* a race of about 500 miles from Toulouse to Brussels, was inaugurated in 1881, in which year the first regular races in Great Britain took place.

The sport was introduced into the United States about the

year 1855 although regular racing did not begin until 1878. Since then it has gained widespread popularity. The speed depends very greatly upon the state of the atmosphere. In the race from Montargis to Brussels in 1880 in bright and clear weather all the prize winners made the distance of 700 miles within 4 hours while in the same race in 1881 on a thick and stormy day 10 hours passed before the first bird arrived.

**Training**—The loft should be on a commanding site. It is best made in the shape of a large room suitably subdivided protected from vermin and provided with drinking troughs rock salt and crushed mortar for the birds' use. It should be fitted with a sufficient number of nests about 1 ft long 6 in in breadth and height. Arrangements should be made for allowing the pigeons to fly out daily for exercise and they should be trained to re-enter the loft through bolting wires which open inwards only into a small chamber to which an electric arrangement may be fitted so as to sound a bell and warn the owner of the arrival of a bird. The food of birds in training consists of vetch beans maize peas broken rice and millet in various proportions according to the country climate and season of the year the daily allowance for each bird being about 40 grammes weight.

Training should commence in warm weather when the bird is about four months old and consists in taking it out in a closed wicker basket and liberating or tossing it at gradually increasing distances from its loft with several days interval of rest between the flights. The usual preliminary distances are 1 2 5 10 and 15 or 20 miles. These tosses should all be made on the same line between the loft and say some neighbouring city in order that a bird may always have to fly in the same general direction during the season. About room may be expected of birds the first season they do not reach their full distances until about the fifth year. The Belgian fanciers generally divide their birds into two classes one for breeding and the other for racing though the latter are allowed to breed within certain limits. Some fanciers always choose birds with chicks in the nest for long journeys claiming that they return faster with this incentive. A seamless metal ring marked with the owner's name is slipped over the foot of the pigeon when only a few days old and during its racing career the longer wing feathers are stamped with the bird's records. At the start of a race the competing birds are tossed together by a starter who takes the time. Upon being released the homer ascends rapidly in spirals until apparently descriing some familiar landmark on the horizon it will fly straight and swiftly towards it. As the birds enter their home lofts the time is taken by the owner. A bird is not considered to have got home until actually through the door of its loft.

**PIGEON POST** The use of homing pigeons to carry messages is as old as Solomon and the ancient Greeks to whom the art of training the birds came probably from the Persians conveyed the names of Olympic victors to their various cities by this means. Before the electric telegraph this method of communication had a considerable vogue amongst stockbrokers and financiers. The Dutch Government established a civil and military pigeon system in Java and Sumatra early in the 19th century the birds being obtained from Baghdad. Pigeons were employed during the siege of Paris in 1870-71. This led to a revival in the training of pigeons for military and naval purposes. They have also been used by newspapers for reporting. It has been found very important to establish registration of all birds. In order to hinder the efficiency of the systems of foreign countries difficulties were placed in the way of the importation of their birds for training and in a few cases falcons were specially trained to interrupt the service in war time the Germans having set the example by employing hawks against the Paris pigeons in 1870-71. No satisfactory method of protecting the weaker birds seems to have been evolved though the Chinese formerly provided their pigeons with whistles and bells to scare away birds of prey.

During the World War pigeons were frequently used to bring back messages from advanced positions and often rendered very valuable service, but the development of wireless telegraphy will restrict their uses.

**PIG IRON** Crude cast iron run from the blast furnace directly into moulds. The moulds originally were of sand formed in a way which suggested a nursing litter of pigs (See IRON AND STEEL BLAST FURNACE)

**PIGMENTS** see PAINTS CHEMISTRY OF

**PIGMENTS OF SKIN AND HAIR** The pigment of the skin the pigment of the blood the pigment of the yolk of the egg and the pigment of the butterfly's wing may each be regarded as representative of a chemical group of colouring matters and into those four groups the great bulk of the pigments seen in the animal world may be placed.

**The Pigment of the Skin**—The skin consists of two principal layers—the epidermis or superficial portion and the dermis or deep portion. The dermis is not pigmented in man nor is the epidermis in the so called white races. In the negro the epidermis is densely pigmented the pigment being present in granules. These granules are not uniformly distributed throughout the epidermis which itself consists of many layers of cells but they are confined to the layer of cells next to the dermis and therefore farthest removed from the external surface.

The black pigment of the skin which is called melanin is situated in granules in the deepest layer of endodermal cells namely that placed immediately over the dermis. All the cells of the epidermis really are developed from this layer (the Malpighian layer) the constituents of which divide and work their way towards the surface. It might be supposed that all the epidermal cells should therefore be pigmented but this is not so as they get nearer the surface they lose their pigment. This is well shown in the case of a blister. The fluid forms in the epidermis separating the deeper from the more superficial portion the covering of the blister in a negro is not pigmented.

In man the pigment is present as a quite inert deposit the person being no more negroid at one time than another but in many lower animals this is not so. The frog for instance will at one time be dark at another pale. The melanin in the frog's skin is laid down in special cells known as melanophores these may contract in minute balls in which case the skin is pale or they may expand pushing out branches in all directions in which case they form an almost continuous network of pigmented material.

The degree of expansion of the melanophores is regulated by circumstances the following table being given by Hogben (abbreviated) —

*Normal Responses of Common Frog*

Background	20 C	10 C
Light		
(a) Dry	Pallor	Generally pale
(b) Moist	Pallor	Darkening
Shaded or dark		
(a) Dry	Pallor	Partial darkening
(b) Moist	Darkening	Darkening
Darkness		
(a) Dry	Pallor	Partial darkening
(b) Moist	Darkening	Darkening

Evidently their dark background low temperature and moistness tend to make the melanophores expand. The mechanism by which expansion of the melanophores in the frog is effected is bound up with a remarkable body situated underneath and connected with the brain—the pituitary body (see art. HORMONES). This body secretes no doubt at the bidding of the brain a hormone into the blood which acting on the melanophores causes them to expand.

The pigment cells in the frog unlike those in man are situated at different levels some are in the epidermis and some in the dermis. This arrangement has been exploited very completely by the chameleon. The chameleon possesses two layers of cells each in the dermis. As an example may be taken an animal which alters in colour from a yellow or very pale green through green to something nearly black. The cells of the outermost layer called variously xanthophores leukophores ochrophores iridocytes

and interference cells are yellowish in colour so far as is known these cells do not alter either in shape or tint. Underneath these are the melanophores also a similar but reddish type of cell called erythrophores. To take the melanophores these send processes towards the surface more or less encircling the xanthophores. Darkening in the colour of the chameleon is due to the migration of granules of melanin from the deeper portion of the melanophores into the more superficial tentacles which surround the xanthophore. The actual colour which the animal presents is partly due to the mixture of colours which the various pigment cells present and partly due to the scattering of light between them. The migration of the melanophore granules in the chameleon is due largely to the hormone adrenalin. The current belief that the chameleon takes on the colour of its surroundings is much exaggerated the colour is influenced largely by light and temperature and so far as the author has been able to judge in a very limited way by temper also if the chameleon were annoyed it took on a darker colour.

Fish too have great powers of colour change within a certain scale of colours which scale does simulate very closely the colour of the bottom on which they lie. Their colour change is also wrought by melanophores but these seem more directly to be controlled by the nervous system and less by hormones than those of the frog. Thus if a nerve going to a particular segment of the skin be severed the possibility of colour change appears to vanish.

**The Chemical Nature of Melanin**—Melanin is closely related to two remarkable chemical substances found in the body. The one is the hormone adrenalin (which turns a blackish colour on exposure) the other is a substance tyrosine which is one of the breakdown products of protein.

The chemistry of melanin formation has been studied chiefly in the vegetable kingdom. A familiar example is seen when an apple is cut and the cut surface is exposed to air. The melanin is formed from tyrosine in the apple by oxidation but the mere exposure of tyrosine to air will not produce melanin. There must also be a ferment present which effects the oxidation. This ferment is called tyrosinase. If two solutions—(1) tyrosine and (2) tyrosinase—both of which are colourless—be mixed and shaken with air the mixture first becomes a reddish colour and gradually turns to a dark brown. The reddish pigment appears to be an intermediate body between tyrosine and melanin. Recently Raper and his colleagues have shown that the role of the tyrosinase lies in the formation of this reddish substance the melanin being a more complicated body derived from the union of two molecules of this red substance.

The pigments in hair are formed on similar lines to those of skin. H. Onslow the leading authority at the time of his death wrote. The colour of human hair depends upon the colour and form of the pigment (i.e., whether it is diffused or deposited in granules) and upon the (air) vacuoles. In light and sandy hair the pigment is chiefly diffused and of a yellowish red colour but in darker hair the pigment is present as dark brown or black granules. Onslow recognizes three pigments in rabbits giving rise to six colours the pigments being black chocolate and yellow which give rise to rabbits of those colours and when the pigments are diluted to blue fawn and cream respectively. The pigments may however be mixed or in bands giving rise to the agouti. With regard to whiteness Onslow writes. The hair of an animal may be white for one of three reasons—(1) the absence of either chromogen or enzyme (2) the absence of both chromogen and enzyme (3) the presence of an inhibitor of the enzyme.

Whilst most of the pigments in the integument consist either of melanin or some substance closely allied to it a few are of quite a different origin.

The beak and the legs of fowl for instance are often yellow the pigment being one known as carotin—the same that colours the carrot. Its presence is in a sense accidental. It is not manufactured in the animal body but exists in the vegetables eaten. It is absorbed into the blood during digestion and being soluble in fat it accumulates in places where fat exists. More especially is this the case in the yolk of the egg. Hens fed on foods com-

pletely free of pigment after a time lay it with colourless yolks moreover if fed on food containing other soluble pigments the yolk becomes correspondingly coloured egg with bright red yolks are obtained if the dye Sudan III be mixed into the food

It is remarkable that haemoglobin contributes little to the pigmentation of the skin—in man only in pathological conditions. In jaundice the yellow pigment is the same as ordinarily appears in the bile and is practically haemoglobin stripped of its iron and of its protein. Closely related to bile pigment is uroporphyrin which occasionally appears in the skin and then with very distressing results. The skin becomes exceedingly sensitive to light so that the individual requires veiling in the open air otherwise he would suffer from sunburn amounting to inflammation.

Another sort of porphyrin is however found in the integument of some of the lower animals as for instance the brown line on the back of the earth worm. This is protoporphyrin it is the pigment which forms the basis of haemoglobin and is most familiar as being that which colours brown eggs.

Finally the distinction between *pigment* and *colour* must not be forgotten. Black eyes and blue contain the same pigment—melanin—black more than blue but the blue hue is obtained from the way in which the light is reflected from the surfaces of the fibres of which the iris is made and among which a number of pigment cells are disposed. (J BAR)

**PIGOT, GEORGE, BARON** (1819–1877) English governor of Madras was born on March 4 1819 and entered the service of the East India Company in 1836. He became governor and commander in chief of Madras in 1855. Having defended this place against the French in 1858–59 and occupied Pondicherry on behalf of the company he resigned office in November 1863 and returned to England being made a baronet in 1864. In the following year he obtained a seat in parliament which he retained until his death in 1877 he was created an Irish peer as Baron Pigot. Returning to India in 1875 to occupy his former position at Madras Pigot was at once involved in a quarrel with the majority of his council which arose out of the proposed restoration of the rajah of Tanjore. The governor was arrested by order of his opponents and was still a prisoner when he died on May 11 1877. In 1879 the matter was discussed in parliament and four of those who were responsible for his arrest were tried and fined £1000 each. Pigot who left several illegitimate children was never married and his barony became extinct.

**PIG STICKING or HOG HUNTING** is the sport of chasing the wild boar on horseback with a spear. From the earliest times the pursuit of the wild boar has been a favourite pastime in Europe but the modern sport of pig sticking is of Indian origin. It is now generally accepted as a fact that pig sticking was the outcome of bear spearing which was popular amongst British sportsmen in Bengal until the beginning of the 19th century when bears had become so scarce that wild boars were substituted as the quarry. Early in the 19th century it seems that the spear was generally thrown and Captain Johnson writing in 1837 gives directions for throwing the spear which was a weapon more in the nature of a javelin with different coloured ribbons attached to the butt so as to enable the owner to reclaim his spear. In 1830 Mr Mills of the ICS seems to have introduced the jobbing spear in his district and this weapon was universally used in Bengal. But the jobbing or thrusting spear was known before 1830 and was used regularly by officers of Lord Lake's Army as early as 1803 (*vide War and Sport in India an Officer's Diary 1802–1806*). At the present time there are really three types of spear in general use the short Bengal spear which is about 5 feet long and is always used over hand the long Bombay spear which may be as long as 10 to 12 feet and is always used under hand like a lance and a spear about 6 to 7 feet long well leaded at the butt so as to balance about a foot from that end which is generally used under hand but which can should circumstances so demand be used over hand. This last is the type of weapon common in the United Provinces and Delhi districts. The best type of horse is one that is fast and quick, yet not too big as very rapid twists

and turn must be made when following a pig which jinks or turns sharp in its tracks. For this same reason the horse must be perfectly balanced and well back on its hocks while a good shoulder and long rein help it to stand up over bad ground.

A large area of land is controlled and hunted by a Tent Club which corresponds to a Hunt in England and private expeditions after pig in any such area are forbidden by etiquette. A Tent Club is managed by an honorary secretary which is an unfortunate title as this individual has power and prestige similar to those of a M.F.H. in England. The season varies in different districts but begins as soon as the heavy undergrowth which grows up during the monsoon has died sufficiently to enable riding across country usually in January and continues throughout the hot weather until the rains break towards the end of June. April, May and early June are the best months. Meets of a Tent Club take place as a rule once a fortnight and last for two to four days. There are two methods of hunting. Where the whole country is covered with girth high grass and show (tan grass) a long line of beaters advances while the spears ride with the line. These are divided into heats of three or four and only one heat may ride a boar that is put up or reared by the beaters the heat nearest the boar taking the hunt. The rider who gains first spear that is who spears the boar first claims the head and tusks as his trophy. But where the boar inhabits thick patches of unridable jungle as is the case in Central India and Guzerat as well as in isolated cases in other parts the heats wait in hiding outside while beaters drive out the boar. The rules for riding are the same in both cases.

There are various pig sticking competitions the best known of which is the Kadir Cup. The word Kadir (pronounced Karder) merely means the old bed of a large river. All the big Indian rivers are constantly changing their courses and the land which has at one time been under water may be anything from five to thirty miles in width. Such land is a river Kadir and is overgrown with tamarisk and grass intersected with nullahs (i.e. water courses dry or full of water) and dotted with *jhils* (swamps). Villages are few and far between while the ground is the haunt of wild boar and many other species of game both big and small. A large part of the Ganges Kadir has been controlled by the Meerut Tent Club since before the Mutiny and the Kadir Cup is run annually in March in this country. Competitors may enter two horses but not more. Heats of three are determined by lots and the gamer of the first spear in each heat qualifies for the second round and so on to the semi final and final heats. The winning of the Kadir Cup which was instituted in 1869 constitutes the blue ribbon of pig sticking.

Other pig sticking competitions are the Guzerat Cup which is run in Guzerat on similar lines to the Kadir Cup the Nagpur Hunt Cup which goes to the member of the Tent Club who gains the greatest number of first spears in the season and the Muttra Cup which was instituted in 1913 and is awarded to a team of three who actually kill the greatest proportion of boars to those hunted. This event is run in the Jumna Kadir near Muttra.

Pig sticking in India suffered severely during the War owing to the shortage of spears and many old Tent Clubs were automatically disbanded through lack of members and funds. But there has been a great revival since 1919 and almost all the old Clubs have been resuscitated the sport is as popular now as it has ever been in the past and in 1917 one of the largest boars ever recorded as being speared was killed in the Gogra Kadir by the Fyzabad Tent Club. This boar measured 37½ inches at the withers and weighed 35 pounds.

The only other country where pig sticking is practised is in Tangier where there is a flourishing Tent Club.

Useful books on the subject are F. B. Simpson *Letters on Sport in Eastern Bengal* A. E. Wardrop *Modern Pig Sticking* Sir R. S. S. Baden Powell *Pig Sticking or Hog Hunting* (G. Bu.)

**PIGWEEED**, a name applied to various plants especially lamb's quarters (*q.v.*) and various species of amaranth (*q.v.*). The winged pigweed (*Cycloloma atriplicifolium*) of the Great Plains region of North America is closely allied to lamb's quarters. See illustration on page 924.

saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. The Christian pilgrimage arose from devotion to the memory of Jesu the faithful repaired to those places which were invested with memories of their Lord's earthly life. Bethlehem and Jerusalem became objects of such visits from the 2nd century and from references in Eusebius and others it is evident that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer and that men travelled for purposes of prayer implies acceptance of the theory of sanctuaries which it is an act of piety to visit.

#### THE PILGRIMAGE IN THE ANCIENT CHURCH

**The East**—In the passages cited above Bethlehem and the Mount of Olives figure as the main goal of the pilgrim and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. The one holy site in the town of Jerusalem before the time of Constantine was the so-called *Coenaculum* which received its name in later years. It was regarded as the house in which—according to the Acts of the Apostles (xii 12 sqq)—Mary the mother of John Mark lived and the belief was that there the Lord held the Last Supper and that there the eleven assembled after the Ascension.

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites under Constantine the Great as described by Eusebius in his biography of the emperor (iii 5 sqq). At the order of Constantine the accumulation of rubbish covering the supposed site of the burial place of Jesus was removed and the cave was discovered in which Joseph of Arimathea had laid the body of Jesus and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (AD 336). The churches in Bethlehem and on the Mount of Olives were erected by Helena the mother of Constantine who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers and relics of Christ were found in the shape of the Cross and the nails. The result was an exaggerated importance attached to these pilgrimages a view which led to energetic protests especially from Gregory of Nyssa who composed a monograph on the pilgrimages (*De us qui adeunt Hierosol*). Jerome like Gregory insists on the point that residence in Jerusalem has in itself no religious value it is not locality but character that avails and the gates of Heaven are as open in Britain as in Jerusalem (*Ep* 58 3).

But Jerome never denied the religious uses of the pilgrimage he considered it an act of faith for a man to offer his prayers where the feet of the Lord had stood and the traces of the Birth of the Cross and of the Passion were still to be seen (*Ep* 4, 1). With the number of the pilgrims the number of pilgrim resorts also increased. Of Jerusalem alone Jerome relates that the places of prayer were so numerous that it was impossible to visit them all in one day (*Ep* 46 9). In the Holy Land the list was still longer the natives were ready to show everything for which the foreigners inquired and the pilgrim was eager to credit everything. In her expedition to the East Paula the friend of Jerome visited among other places Sarepta and Caesarea. In the first named place she was shown the tower of Elijah in the second the house of Cornelius that of Philip and finally the grave of the four virgins. At Bethlehem she saw in addition to the church of the Nativity the grave of Rachel at Hebron the hut of Sarah in which the swaddling clothes of Isaac and the remains of Abraham's oak were on view (*Hieron Ep* 108).

**In the West**—While pilgrim resorts were thus filling the East, their counterparts began to emerge in the West. And here the starting point is to be found in the veneration of martyrs. Care for the tombs of martyrs was sanctioned by immemorial custom of the Church but, in this case also, a later age failed to preserve

the primitive conception in its purity and Augustine himself was obliged to defend the usage of the Church from the imputation that it implied a transference of heathen ceremonial to the sphere of Christianity (*Contr. Faust* ix 1). The martyrs were the local heroes of particular communities but there were men whose life and death were of significance for the whole of Christendom—the apostles. Of these Peter and Paul had suffered martyrdom in Rome and it was inevitable from the nature of the case that their graves should soon become a resort not only of Romans born but of stranger also. The Roman *campus martium* were visited by numerous pilgrims even in the 4th century for the earliest *graffiti* in the papal crypt of the Coenaculum Callisti must date from this period (*De Rossi Roma sotterranea* 1 55 sqq. *Kir u Rom Sott* 148 sqq.).

Pilgrims were drawn to the graves of the saints convinced that there divine succour was certain hence came the belief in a never ending series of miracle there performed. Doubt was unknown. St Augustine observes that though Africa was full of martyrs' tombs no miracle had been wrought at them so far as his knowledge extended. This however did not lead him to doubt the truth of those reported by others—a fact that is somewhat surprising when we reflect that the phenomenon caused him much disquiet and perplexity. What he asks can fathom the design of God in ordaining that this should happen at one place and not at another? And eventually he acquiesces in the conclusion that God who gives every man his individual gift at pleasure has not willed that the same powers should have efficacy at every sepulchre of the saints (*Ep* 8 3).

#### THE PILGRIMAGE IN THE MIDDLE AGES

The mediaeval Church adopted the custom of the pilgrimage from the ancient Church. The young Germanic and Romance nations did peculiarly as the Greek and Romans had done before them and the motives of these devotional journeys—now much more difficult of execution in the general decay of the great world system of commerce—remained much the same. They were undertaken to the honour of God for purposes of prayer or in quest of assistance especially health. But the old causes were reinforced by others of at least equal potency. The mediaeval Church was even more profoundly convinced than its predecessor that the miraculous power of Deity attached to the bodies of saints and their relics. But the younger nations—French English and German—were scantily endowed with saints while on the other hand the belief obtained that the home countries of Christianity especially Rome and Jerusalem possessed an inexhaustible supply of these sanctified bodies.

Pilgrimages were consequently undertaken with the intention of securing relics. At first it was enough to acquire some object which had enjoyed at least a mere connection with the hallowed corpse. One enthusiast took a little wax dropped from the taper another a portion of the dust which lay on the grave a third a thread from the cloth covering the sarcophagus still another plucked the flowers which visitors had planted above the tomb. Before long however these humble trophies failed to content the pilgrims and they began to devote their efforts to acquiring the actual bodies or portions of them—frequently by honest means still oftener by trickery. One of the most attractive works of early mediaevalism—Einhard's little book *Translatio Marcellini et Petri*—gives a vivid description of the methods by which the bodies of the two saints were acquired and transported from Rome to Seligenstadt on the Main.

Far more important consequences however resulted from the fact that the mediaeval mind associated the pilgrimage with the forgiveness of sins. This conception of the pilgrimage as a means of expiation or a source of pardon for wrong was foreign to the ancient Church. It is quite in accordance with the keener consciousness of sin which prevailed in the middle ages that the expiatory pilgrimage took its place side by side with the pilgrimage to the glory of God. The pilgrimage became an act of obedience and in the books of penance (*Poenitentiale*) which date from the early middle ages it is enjoined as an expiation for many of the more serious sins especially murder or the less venial forms of

unchastity. The place to be visited was not specified but the pilgrim who was bound by an open letter of his bishop to atone himself as a penitent lay under the obligation wherever he went to repair to the churches and—more especially—he to the saints and there offer his prayers. On occasion a chain or ring was fastened about his body that his condition might be obvious to all and soon all manner of fables gained currency how here or there the iron had sprung apart by a miracle in token that the sinner was thereby absolved by God.

As the system of indulgences (*q v*) developed a new motive came to the fore which rapidly overshadowed all others. Pilgrimages were now undertaken to some sacred spot simply in order to obtain the indulgence which was vested in the respective church or chapel. In the 11th century the indulgence consisted in a remission of part of the penance imposed in the confessional in return for the discharge of some obligation voluntarily assumed by the penitent. Among these obligations a visit to a particular church and the bestowal of pious gifts upon it held a prominent place and during the whole period of mediaevalism the number of pilgrims was perpetually on the increase.

**The Pilgrim Resorts**—The most important places of resort both for voluntary and involuntary pilgrimages were still Palestine and Rome. On the analogy of the old *Itineraria* the abbot Adamnan of Iona (d. 104) now composed his monograph *De locis sanctis* which served as the basis of a similar book by the Venerable Bede (d. 105). His authority was a Frankish bishop named Arculf who resided for nine months as a pilgrim in Jerusalem and visited the remaining holy sites of Palestine in addition to Alexandria and Constantinople. Of the later itineraries the *Descriptio terrae sanctae* by the Dominican Burchardus de Monte Sion enjoyed the widest vogue. This was written between the years 1185 and 1195 but books of travel in the modern tongues had already begun to make their appearance. The initiative was taken by the French in the 11th and 12th centuries and the Germans followed in the 14th and 15th while the *Book of Wayes to Jerusalem* of John de Maundeville (c. 1336) attained extreme popularity and was translated into almost all the vernacular languages.

As a result of this steady increase in the number of pilgrims the old arrangements for their accommodation were found deficient. Consequently hospices arose which were designed exclusively for the pilgrim. Those on the Alpine passes are common knowledge. The oldest that on the Septimer pass dates from the Carolingian period though it was restored in 1110 by the bishop Wido of Chur that on the Great St. Bernard was founded in the 10th century and reorganized in the 13th. To this century may also be assigned the hospice on the Simplon to the 14th those on the St. Gothard and the Lukmanier. Similarly the Mediterranean towns and Jerusalem in particular had their pilgrim refuges. Service in the hospices was regularly performed by the hospital fraternities—that is to say by lay associations working under the authorization of the Church. The most important of these was the fraternity of the *Hospitale iherosolymitanum* founded between 1065 and 1075 for hence arose the order of St. John the earliest of the orders of knighthood (See ST. JOHN OF JERUSALEM KNIGHTS OF). In addition to the hospital of Jerusalem numerous others were under its charge in Acre, Cyprus, Rhodes, Malta, etc. Associations were formed to assist pilgrims bound for the East, one being the *Confrérie des pelerins de Terre Sainte* in Paris founded in 1155 by Louis de Bourbon count of Clermont (afterwards first duke of Bourbon).

But since in the middle ages the Holy Land was no longer held by a Christian Power the protection of the pilgrims was no less necessary than their sustenance. This fact after the close of the 11th century led to the Crusades (*q v*) which in many respects are to be regarded as armed pilgrimages. For the old dream of the pilgrim to view the country where God had walked as man lived on in the Crusades—a fact which is demonstrated by the letters of Bernard of Clairvaux with the songs of Walther von der Vogelweide and other Crusaders. And since the strongest motive in the pilgrimage was the acquisition of indulgences unnumbered thousands were moved to assume the Cross when in

1099 Urban II promised them plenary indulgence. The conquest of Jerusalem and the erection of a Christian empire in Palestine naturally welled the influx of pilgrims. And though in 1187 the Holy City again fell into the hands of the infidel while in 1191 the loss of Acre eliminated the last Christian possession in Palestine the pilgrimages still proceeded. It was not till the Reformation the wars of the 16th century and the loss of Rhodes, Candia and Cyprus to the Turks that any appreciable alteration was effected. When Ignatius de Loyola (*q v*) sailed in 1533 from Venice to Palestine only some thirteen souls could be mustered on the pilgrimage while eleven or nine others sailed with the Venetian state vessel as far as Cyprus. A considerable number had abandoned their pilgrimage and returned home on the news of the fall of Rhodes.

For pilgrimage to increase as it was styled the permission of the Church was still requisite. The pilgrims made their journey in grey cowl fastened by a broad belt. On the cowl they wore a red cross and a broad brimmed hat, a staff, sack and gourd completed their equipment. During their travels the beard was allowed to grow and they prepared for departure by confession and communion. Of their hymns many are yet extant (*Jerusalem mirabilis*, *In Gottes namen faren wir*, etc.). Ships belonging to the knights of St. John and the Knights Templars conducted the commerce with Palestine and the pilgrims formed themselves into unions elected a master and concluded their agreements as to the outward voyage and return in common. The expense of the journey to Palestine were no light matter. In the 11th century they may be estimated at 100 marks of silver (£100) for the ordinary pilgrim. The expenses of the princes and lords were of course much heavier. Duke William of Saxony who was in Jerusalem in 1461 spent no less than £10,000 on his journey (See Prutz *Kulturgeschichte der Kreuzüge* pp. 106 sqq. Rohricht *Deutsche Pilgerreisen* p. 4).

Great as was the number of pilgrims overseas it was yet far exceeded by that of the visitants to the threshold of the apostles in Rome which received their greatest impetus through the inauguration of the so-called Year of Jubilee.

Of the other pilgrim resorts we shall only emphasize the most important. Priority of mention is due to St. James of Compostella (Santiago in the Spanish province of Galicia). Here the attraction for the pilgrim was the supposed possession of the body of James the son of Zebedee. The first connection of the apostle with Spain is to be traced in the *Poema de aris b Mar et xu apostolic* which is ascribed to Aldhelm (d. 709) and contains a story of his preaching in that country. The earliest account of the transference of his relics to the Peninsula is found in Notker Balbulus (d. 91) *Martyrol in Jul xxv*. But in Spain belief in this cherished possession was universal and step by step the theory won credence throughout the West. In England indeed the shrine of St. James of Compostella became practically the most favoured devotional resort and in the 11th century its visitation had attained such popularity that a pilgrimage thither was ranked on a level with one to Rome or Jerusalem. In France St. Martin remained the chief goal of the pilgrim while Notre Dame de Sous Terre in Chartres (with a portrait of the black Virgin) Le Puy en Velay (dep. Haute Loire) and others also enjoyed considerable celebrity. In England pilgrimages were made to the tomb of the murdered archbishop Thomas a Becket in Canterbury Cathedral. The setting of Chaucer's *Canterbury Tales* gives a vivid idea of the motley company of pilgrims but it seems probable that Germany also sent a contingent. In addition Walsingham, Peterborough, St. David's, Holywell and St. Andrews in Scotland were much frequented. In lower Germany Cologne and Aix-la-Chapelle in Switzerland Einsiedeln were the principal resorts.

In Italy the church of the Archangel on Mt. Gargano was one of the most ancient centres of the pilgrimage. Later the Portiuncula church at Assisi displaced all other resorts with the exception of Rome but in the 15th century it was overshadowed in turn by the 'Holy House' at Loretto on the Adriatic. According to an extravagant legend the house of Joseph and Mary in Nazareth was transported by angels on the night of the 9th–10th of May

191 to Dalmatia then brought to the Italian coast opposite (Dec 10 191) till on the 14th of September 195 it found rest on its present site. The pilgrimage thither must have attained great importance as early as the 13th century for the popes of the Renaissance found themelves constrained to erect an imposing pilgrim church above the Holy House.

The significance of the pilgrimage for the religious life of later mediaevalism cannot be adequately estimated. The possession of any extraordinary relic was everywhere considered a sufficient claim for the privilege of indulgences and wherever this privilege existed there the pilgrims were gathered together. All these pilgrimages great and small were approved and encouraged by the Church. And yet during the whole of the middle age the voice of suspicion in their regard was never entirely stilled. Earnest men could not disguise from themselves the moral dangers almost inevitably consequent upon them; they recognized moreover that many pilgrims were actuated by extremely dubious motives and they distrusted the exaggerated values set on outward works. The Roman papacy had no more zealous adherent than Boniface yet he absolutely rejected the idea that Englishwomen should make the journey to Rome and would willingly have seen the princes and bishops veto these pilgrimages altogether (*Ep* 78). The theologians who surrounded Charlemagne held similar views.

When the abbess Ethelburga of Fladbury (Worcestershire) found her projected pilgrimage impracticable Alcuin wrote to her saying that it was no great loss and that God had better designs for her. Expend the sum thou hast gathered for the journey on the support of the poor and if thou givest as thou canst thou shalt reap as thou wilt (*Ep* 300). Bishop Theodulf of Orleans (d 811) made an energetic protest against the delusion that to go to Rome availed more than to live an upright life (*Carm* 67). To the same effect the synod of Chalon sur Saône (813) reprobated the superstition which was wedded to the pilgrimage (*c* 13) and it would be easy to collect similar judgments delivered in every centre of mediaevalism. But fundamentally pilgrimages in themselves were rejected by a mere handful; the protest was not against the thing but against its excrescences.

**The Modern Pilgrimage**—The Reformation eradicated the belief in the religious value of visits to a particular locality. It is only pious memory that draws the Protestant to the sites consecrated by ecclesiastical history. On the other hand while in the Eastern Church things have undergone little change the developments in the Roman Church show important divergences. The Year of Jubilee in 1550 was unprecedented in its scant attendance but the jubilees of 1575 and 1600 again saw great armies of pilgrims marching to Rome (*see* JUBILEE YEAR OF). Fresh pilgrim resorts sprang up mediaeval shrines which had fallen on evil days emerged from obscurity. The 19th century led to an extraordinary revival of the pilgrimage. Not only did new resorts spring into existence—e.g. La Salette in Dauphine (1846) and more particularly Lourdes (1858) in the department of Hautes Pyrenees—but the numbers once more attained a height which enables them to compete with the mediaeval figures. The dedication of the church of Lourdes in 1876 took place in the presence of 30 bishops, 3000 priests and 100000 pilgrims. No new motives for the pilgrimage emerged in the 19th century unless the ever increasing cultus of the Virgin Mary may be classed as such; all of the new devotional sites being dedicated to the Virgin. For the rest the desire of acquiring indulgences maintains its influence but doubting voices are no more heard within the pale of the Roman Catholic Church.

Marx, *Das Wallfahrten in der katholischen Kirche* (1842). article 'Pilgrimage' in Hastings *Encyclopaedia of Religion and Ethics* (dealing with the custom as rooted in Mohammedan, Babylonian, Buddhist, Hindu and Japanese religions as well as in Judaism and Christianity), with numerous references.

**PILGRIM FATHERS** In American history Pilgrims is applied to the earliest settlers of the colony of Plymouth Mass and its more specific application is to the first emigrants who sailed in the Mayflower in 1600. They were from the beginning Separatists from the Church of England; they had established Independent (Congregational) churches at Scrooby and Gainsborough early in the 17th century and some of them had fled to Amsterdam in 1608 to avoid persecution and had moved to Leyden in the following year. They sailed from Delft haven late in July 1600 from Southampton on the 1st, from Plymouth on Sept 6 and late in Dec 1600 founded the colony of Plymouth Massachusetts (*see* MASSACHUSETTS, PLYMOUTH and MAYFLOWER).

**PILGRIMS' WAY, THE** From Winchester in Hampshire England to Canterbury in Kent runs a road or way which can still be traced now on the present made roads now as a lane, bridle path or cart track now only by a line of ancient yew hollies or oaks which once bordered it. To this old track the name of Pilgrims Way has been given for along it passed the stream of pilgrims coming through Winchester from the south and west of England and from the continent of Europe by way of Southampton to Canterbury Cathedral to view the place of the martyrdom of Thomas Becket in the north transept; the relics in the crypt where he was first buried after his murder in 1170 and the shrine in the Trinity Chapel which rose above his tomb after the translation of the body in 1190. There were two festivals for the pilgrimage on the 9th of December the day of the martyrdom and on the 17th of July the day of the translation. The summer pilgrimage naturally became the most popular. In 1538 the shrine was destroyed and the relics of the saint scattered but the great days of the pilgrimage had then passed. Erasmus gives a vivid picture of the glories of the shrine and of all that the pilgrims saw on his visit with Colet to Canterbury in 1514.

This road although its name of the Pilgrims Way has for long confined it to the road by which the pilgrims came to Canterbury from Winchester follows a far older track. Right back into British and even older times the main direction which commerce and travellers followed across southern and western England to the Straits of Dover and the Continent lay from Canterbury along the southern chalk slope of the North Downs to near Guildford then by the Hoar Road to Farnham. At this point the oldest track went across Salisbury Plain towards Stonehenge and so on to Cornwall. From Farnham westward the only portion of this the oldest track that can now be traced is a small portion that still bears the name of the Harrow (i.e. hoary old) road. It was in early times abandoned for the road from Winchester to which the stream of travel and commerce from the Continent and the south and south west of England was diverted.

The ancient road has been traced fully in Mrs Ady's book *The Pilgrims Way* (1803) and the older track in the fullest detail in Hilaire Belloc's *The Old Road* (1904).

**PILKINGTON, FRANCIS** (d 1638) English madrigal composer the details of whose early life are obscure took his Mus B at Lincoln College Oxford. He was attached to Chester Cathedral about 1604 and a few years later was ordained. His chief works include a book containing 21 vocal pieces and a pavin for the lute and bass viol (1605) *The First Set of Madrigals and Pastorals* (1614) and *The Second Set of Madrigals and Pastorals* (1624).

**PILLAU**, a seaport and watering place in the Prussian province of East Prussia on the spit of sand (*Nehrung*) which separates the Frische Haff from the Baltic on the north of the entrance channel and 29 m by rail from Königsberg. Pop (1933) 7092. Pillau is the place where Gustavus Adolphus of Sweden landed in 1626. It did not obtain civic privileges until 1725 but was fortified shortly after that date. It has a harbour which serves as the outer port of Königsberg and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900-1901 constructed across the Frische Haff from Pillau to Königsberg. Pillau has a school of navigation and is a well known pilot station. Ship building and fishing are carried on.

**PILLNITZ**, a village in the republic of Saxony, situated on the right bank of the Elbe, 5 m above Dresden. Pop (1933)

131 The new palace was built in 1818 on the site of a building which was burnt. The place became a residence of the electors of Saxony about 1700. By the convention of Pilnitz in August 1791 the emperor Leopold II and Frederick William II king of Prussia agreed to take common action against any attack on the part of France.

**PILLORY**, an instrument of punishment which consisted of a wooden post and frame fixed on a platform raised several feet from the ground behind which the culprit stood his head and his hands being thrust through holes in the frame (as are the feet in the stocks) so as to be held fast exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle which secured the heads and hands of several persons at the same time but it was commonly capable of holding only one.

In the statutes of Edward I it is enacted that every pillory or stretch neck should be made of convenient strength so that execution might be done on offenders without peril to their bodies. It was customary to shave the heads wholly or partially and the beards of men and to cut off the hair and even in extreme cases to shave the heads of female culprits. By the Statute of the Pillory (1266) the pillory was made the penalty for many small offences. In 1637 an attack was made on the Press and the pillory became the recognized punishment of those who published books without a licence or labelled the Government. In 1816 the pillory was abolished except for perjury and subornation and the perjurer Peter James Bossy was the last to stand in the pillory at the Old Bailey for one hour on June 2, 1830. It was finally abolished in 1837 at the end of William IV's reign. In France the pillory called *carcan* was employed till 1832. In Germany it was known as *pranger*. The pillory was used in the American colonies and provisions as to its infliction existed in the United States statute books until 1839; it survived in the State of Delaware until 1905 (See STOCKS).

**PILNYAK** (1894— ) Russian novelist. Boris Andreevich Vogau, who later took the pen name of Pilnyak, was born on Sept. 29, 1894 in Mojaisk, Moscow province. His childhood and early youth were spent on the Volga and among the peasants and the land administration intellectuals. He studied economics at the Moscow commercial institute and began publishing stories in 1915. During the Bolshevik revolution Pilnyak lived in Moscow and also travelled through Russia studying the new conditions. In 1933 he visited England and Germany. His works deal with the first chaotic stage of transition from the old Tsarist Russia to the new world of the Soviet Republic. He is the most prominent figure in post-revolutionary fiction. His sympathies are with the peasants as opposed to the town and his stories are deliberately fragmentary and read like diaries and chronicles. His *Tales of the Wilderness* was translated by F. O. Dempsey (1941).

**PILOCARPINE** This alkaloid (see ALKALOIDS) is a colourless oil which occurs in *Jaborandi* leaves along with iso pilocarpine and the related alkaloid pilosine  $C_{10}H_{15}ON$  (Pyman 1912). Pilocarpine  $C_{11}H_{15}ON_2$  was isolated independently by Hardy and by Gerrard in 1875. It boils at 260° C under 5 mm pressure, is freely soluble in water, alcohol or chloroform but not in ether or petroleum and is dextro rotatory in solution. The salts crystallize well; the nitrate which melts at 178° C and the hydrochloride whose melting point is 204–205° C being those used in medicine. On evidence provided mainly by Jowett in England and Pinner in Germany a generally accepted constitutional formula for pilocarpine and isopilocarpine which are regarded as stereoisomerides has been put forward.

**PILONA**, a town of northern Spain on the Infiesto Oviedo railway in the province of Oviedo, between the right bank of the river Pilon, a left hand tributary of the Sella, and the Sierra de Abes (3,268 ft). Pop. (1930) 17,533. Pilon is a densely populated mining and agricultural district.

**PILOTAGE**, as it is now understood, may be described as the art of conducting a vessel in or out of harbour or in the neighbourhood of navigational dangers. The word 'pilot' was formerly used to designate the steersman and later the sailing

master. In fact the art of piloting was divided into two parts: proper piloting identical with what we now term navigating (see NAVIGATION) and common piloting identical with the meaning of the word as given above. See PILOTAGE LAWS.

**PILOTAGE LAWS** The present general British pilotage laws are contained in the Pilotage Act 1913 which Act consolidated and amended the laws of pilotage as they existed under the Merchant Shipping Act 1894. On the passing of the former Act the Board of Trade as the central authority held enquiries with the result that pilotage orders were made by it in respect of each District. Each pilotage order defines the limits of the district, names the pilotage authority therefor, states whether pilotage is compulsory or not therein and empowers the authority to delegate any of its powers or duties to a pilotage committee on which may sit representatives of both pilots and shipowners. The pilotage authority makes the necessary laws for the regulation of pilotage and pilots in its district but these do not take effect until they are confirmed by the Board of Trade.

The principal pilotage authority is the Corporation of Trinity House, London, exercising jurisdiction in the London district which extends from Orfordness to Selsea Bill and in 38 other districts round the coasts of England and Wales. There are however about 60 other districts within which other pilotage authorities have jurisdiction.

**Compulsory Pilotage.**—A ship whilst navigating in a district in which pilotage is compulsory for the purpose of entering, leaving or making use of any port in that district is required to be either under the pilotage of a licensed pilot of the district or under the pilotage of a master or mate possessing a pilotage certificate for the district who is bona fide acting as master or mate of the ship. A ship carrying passengers (other than an excepted ship) is however compelled to be under pilotage irrespective of whether the district in which she is navigating is a compulsory one or not. Under the Aliens Restriction (Amendment) Act 1919 pilotage certificates cannot be granted to aliens except to masters or mates of French nationality trading to the ports of Newhaven or Grimsby.

The following ships are excepted from compulsory pilotage: (1) Ships belonging to His Majesty; (2) Pleasure yachts; (3) Fishing vessels; (4) Ferry boats; (5) Ships of less than 50 tons gross tonnage; (6) Ships exempted by by-law; (7) Tugs, dredgers, sludge vessels, barges and other similar craft belonging to or hired by a dock, harbour or river authority; (8) Ships calling at a port in a pilotage district for the sole purpose of taking on board or landing a pilot belonging to some other pilotage district.

The Board of Trade has the power on the representation of parties interested to revoke or vary any by-laws in a pilotage district or require the pilotage authority to make by-laws. The licensing of a pilot by a pilotage authority does not involve any liability on the part of the authority for any loss occasioned by any act or default of the pilot.

**Pilot Boats.**—All pilot boats regularly employed in any district must be approved and licensed by the pilotage authority for that district who may appoint or remove the masters thereof. Every pilot boat must be distinguished by the name of her owner and port on her stern and her number on each bow and the hull of the boat is usually painted black. When afloat the pilot boat must fly a red and white horizontal flag known as a pilot flag in a conspicuous position. A pilot flag must also be displayed by a vessel having on board a licensed pilot for the district or a master or mate holding a pilotage certificate. The master of a ship subject to pilotage in a district must, under a penalty, display a pilot signal and keep it displayed until a licensed pilot comes on board and if the master accepts the services of a pilot he must give him facilities for getting on board.

The following persons are liable to pay pilotage dues for any ship for which the services of a licensed pilot have been obtained: (a) the owner or master or (b) the consignees or agents who have paid or are liable to pay any other charges on account of the ship and these dues may be recovered in the same manner as fines under the Merchant Shipping Act 1894. The pilotage dues on foreign ships, subject to compulsory pilotage, trading to and from

the port of London have to be paid to the chief officer of customs and excise in that port and such a ship may be detained until such dues are paid. It is an offence punishable by a fine if a licensed pilot demands or receives and a master offers or pays dues in respect of pilotage services at any other rates whether greater or less than those which are fixed by law.

Under section 633 of the Merchant Shipping Act 1894 the owner or master of a ship was not answerable to any person for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of that ship within any district where the employment of a qualified pilot was compulsory by law. Section 13 of the Pilotage Act 1913, however, reversed this defence of compulsory pilotage and enacted that the owner or master of a vessel navigating under circumstances in which pilotage is compulsory is answerable for any loss or damage caused by that vessel or by any fault of her navigation in the same manner as he would if pilotage were not compulsory. Section 13 of the Pilotage Act 1913 did not however come into effect until January 1, 1918, on which date section 633 of the 1894 Act was repealed. The difference which formerly existed under the Merchant Shipping Act 1894 between British law and the law of most foreign countries as to the civil liability of the owner or master of a vessel employing a pilot under compulsion of law has therefore been removed since January 1, 1918.

See *The Pilotage Act 1913 Report of Departmental Committee on Pilotage 1911* Digby & Cole *Pilotage Law* (1913) (W J T H)

#### UNITED STATES

The power of administering all matters relating to pilotage was acquired by the Federal Government as incidental to the authority conferred on it under the Constitution. The first legislative action of the new Government was in 1789 when it deleted its authority to the several States until further provision is made by Congress. Further legislation enacted subsequently has restricted the broad powers conferred in 1789 but the power of the Federal Government is exclusive only when it is exercised. State laws regarding pilotage are operative so long as they are not in conflict with Federal laws.

Among the acts of the Federal Government restricting the manner in which the several States may control pilotage are laws which apply to pilotage on waters that are boundaries between States permitting the master of a vessel to employ a pilot licensed by either State to pilot the vessel to or from such ports, laws which prohibit discrimination in rates or pilotage as between vessels operating solely between ports in the State and those engaged in interstate traffic, laws which provide that all coastwise seagoing steamships shall be under the control and direction of pilots licensed under Federal authority, and laws which prohibit State pilots from levying pilotage on coastwise seagoing steamships.

**Number and Appointment of Pilots**—In many States no maximum or minimum restriction is placed by statute on the number of pilots that may be appointed the number being left to the discretion of the several pilotage authorities. In some cases both a maximum and minimum number are prescribed by law and in other States only a maximum number is mentioned. As a rule pilots are licensed by the local pilotage authority but in several States they are appointed by the governor. In a majority of the States pilots are licensed for life and lose their licences only because of negligence, incapacity, misconduct or infirmity. In the remaining States licences are granted for periods of one to four years and are renewable. Several grades of licences are generally issued the grade varying with the draft of vessel which the holder of the licence is considered competent to conduct.

**Qualification of Pilots**—In all States the primary qualification for appointment as pilot is actual experience in piloting vessels. A number of States require that applicants for licences as pilots must have served an apprenticeship of a specified number of years on boats of the pilots' association either in accordance with the law of the State or by regulation of competent authority.

**Authority**—In the United States, a pilot occupies the status of an officer of the ship when on board in the exercise of his duty

and his order as such must be obeyed by the crew. When the master is on board the orders of the pilot are considered to be those of the masters. The pilot is subject to the master in the matter of discipline but is not liable to any ship's duty except that of pilot. Once in charge of a vessel at sea it is the duty of the pilot to stay by the ship until she reaches her destination or some place of safe anchorage unless he is earlier discharged.

**Liability of Pilots**—Pilots are generally required to give bond usually \$ 500 to secure the faithful performance of their duties and for the payment of all damages that may accrue from their negligence or unfaithfulness. The bond is not required in some States, the amount is not specified in the laws of others and in still others it is fixed. The courts have held that while a pilot is responsible to the owner of a vessel for negligence or default in the performance of this duty, he is not liable for the vessel's loss when he has used his best skill and judgment although the result shows that his best judgment was wrong.

**Compulsory Pilotage**—Pilotage is generally compulsory upon certain vessels or classes of vessels approaching or departing from a harbour. Throughout the States all public vessels of the United States and all steamships engaged in the coasting trade are exempt from compulsory pilotage. In respect to other vessels or classes of vessels there is wide variation in the laws of the several States. In the great majority of States compulsory pilotage is prescribed for all vessels both of domestic and foreign registry engaged in foreign trade but not for any class of vessel in the domestic trade. In general the rule is that there has been a tender of the services of a pilot if there has been displayed the customary pilot signal on the usual cruising ground of pilot boats at sea and there is a visible approach of the boat towards the incoming vessel. If the offer of pilot service is refused the pilot becomes entitled to full fees or half pilotage according to the local State law and the liability for payment is enforceable in admiralty.

**Compensation**—In general pilotage fees are fixed by statute based on the draught of the vessel. In some cases the rates are prescribed by the local pilotage authorities and the net tonnage of the ship is a factor in determining the pilotage charges. In a number of States where pilotage is compulsory the full rate is not charged if the services of a pilot are refused. The various statutes commonly provide that pilotage fees are to be paid by and are recoverable from the master or owners of the vessel. In addition to fees for the actual work of pilotage the statutes of practically every State permit certain extra charges to be made to cover loss of time occasioned by detention of vessel in quarantine or by carrying the pilot to sea when the pilot boat was ready to take him off.

**Pilot Boats**—The days when a large number of sailing vessels were in the pilot service off the principal ports, each vessel owned and operated independently have given way. In 1929 at practically every large port in the United States all of the licensed pilots belong to an association owning and operating one or more specially constructed steamers which are maintained on the pilotage grounds usually at the bar. These grounds are well known to mariners who may safely count on finding there at practically all times a pilot boat displaying the Union Jack with a sufficient number of pilots aboard to accommodate any reasonable number of vessels seeking to enter the port.

**BIBLIOGRAPHY**—For legislation on pilotage in the United States see the Revised Statutes and the Statutes at Large of the United States and the statutes of the several States in which pilot service is maintained particularly Title 46 U.S. Code, Laws of 1909, New York Ch. 42, Sec. 56, Revised Laws of Mass. 1902 as amended, Civil Code of 1906, California Sec. 2036. (C M A)

**PILOT-FISH** (*Naucratus ductor*) a pelagic fish of the family of horse mackerels or *Carangidae* well known to sailors from its habit of keeping company with ships and large fishes especially sharks. It occurs in all tropical and subtropical seas and is common in the Mediterranean. In summer pilot fish accompany ships into port as far north as the south coast of England. It accompanies both ships and sharks on account of the supply of food which it derives from them as does the remora (*q.v.*). All observers however agree that neither the

pilot fish nor the sucking fish is ever attacked by the shark. The pilot attains to a length of about 1 m. A sharp keel runs along the middle of each side of the tail. The teeth are small arranged in bands. On a bluish ground colour five to seven dark blue or violet cross bands traverse the body from back to belly. The pilot fish spawns in the open sea.

**PILOTY, KARL VON** (1826–1886) German painter born at Munich on Oct. 1, 1826, was the son of Ferdinand Piloty (d. 1844) noted as a lithographer. His picture of *Seni at the Dead Body of Wallenstein* (1855) soon gained for the young painter the membership of the Munich Academy where he succeeded Schorn (his brother-in-law) as professor. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated *Discovery of America*. In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany. He was a successful teacher and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max and Grützner. He died at Munich on July 21, 1886.

**PILSEN** or **PLZEN**, the second town of Bohemia, Czechoslovakia, at the confluence of the Radbuza and Mže in a fertile and productive fruit and cereal basin. The vicinity is rich in coal and iron. The staple product is beer exported to all parts of the world which is closely followed by iron and steel goods and machinery mainly from the Skoda factory, the greatest in the republic. Spirits, leather goods, paper and earthenware are also produced in large quantities. The town is the trade and transport centre for the whole of south-west Bohemia and its cereal and cattle markets are famous.

Little is known of Pilsen till the 10th century and it did not become a town till 1172 but since then it has figured largely in Bohemian history and was a centre of Catholic resistance during the Hussite wars. Among its sights are the 15th century Gothic church with a tower 35 ft high and a 16th century Renaissance town hall. Pop. (1930) 114,150.

**PILSUDSKI, JOSEPH** (1867–1935) Polish soldier and statesman, born in Nov. 1867 in Żulow (Zulowo) County of Wilna (Wilno) of an ancient family tracing their origin from the Lithuanian Princes of Ginet and educated at Wilno and Kharkov.

In 1887 Pilsudski was involved in an anti-Tsarist plot and sentenced to five years' penal servitude in Eastern Siberia although the trial clearly established his innocence and his deprecation of terrorist methods. He returned to Wilno in 1890 and formed the Polish Socialist party (PPS). In 1894 he began the *Robotnik* (The Workman), a secret paper of radical tendencies edited, printed and distributed by Pilsudski himself. He was already a force. His courage, keen sense of humour, attractive personality and good breeding made him the idol of the working classes; he was revered by the intelligentsia for the tenacity of his convictions for his fearlessness and his iron will.

His activities increased rapidly. Armed resistance against atrocities of the Russian government was introduced into the party programme. Armed detachments of workmen protected meetings and demonstrations against the police and military and bloodshed became frequent. In 1900 Pilsudski and his wife Marie Tuszkievicz, whom he had married in 1894, were arrested in the offices of the *Robotnik* in Łódź and for a year he was kept in a special cell in the notorious Tenth Pavilion of the Warsaw Citadel. Simulating insanity, Pilsudski was transferred to the St. Nicholas Hospital in St. Petersburg where his friends rescued him by an ingenious plot on May 13, 1901. He lived in London for some time following his escape from imprisonment and returned to Cracow in 1902.

During the Russo-Japanese war Pilsudski planned an insurrection. Frustrated through lack of munitions, he visited Japan to enlist her support but again proved unsuccessful. After the Russian revolution of 1905 and the convocation of the Duma, Polish revolutionary activities were discontinued but the Russian Constitutional government continued the policy of its predecessors with regard to Poland. Pilsudski transferred his headquarters to Cracow and Lwów and commenced his activities

among the refugees from the Russian provinces of the country. Here the idea of a private Polish army was conceived. An officers' school was established in Lwów and branches of the *harcho* (*strzele*) formed throughout Galicia. Following the World War, Pilsudski hoped for a German and Austrian victory over Russia and a French victory over Germany. When war broke out, he consequently sided with Austria. The total strength of his army was 5,000 infantry and a squadron of cavalry in uniformly armed and equipped. The remaining 500 of his men were dispatched to Hungary by the Austrian general command. His brigade took part in numerous battles in which it exhibited great bravery and exemplary discipline while Pilsudski himself displayed the highest qualities as a leader. He refused, however, to let his legions be used outside of Polish territory. On the collapse of Russia, he turned against Germany and Austria. In July 1916 he resigned the command of the Polish legions in consequence of the abuses of the German and Austrian occupation authorities in Polish territory. At the same time he sought to establish relations with France and Great Britain through his colleagues MM. Sokolnicki and Narutowicz. On Nov.

1916 the independence of Poland was proclaimed by the Central Powers and Pilsudski accepted the position of Minister of War in the newly formed Council of State. Within a short time he formed the semi-secret Polish military organization *ie Polska Organizacja Wojskowa* (POW) which spread throughout the country and helped to disarm Germans and Austrians in 1918.

When the Polish legions in Russia, commanded by Gen. Musnicki, proclaimed Pilsudski their spiritual leader and when his own legions refused in July 1918 to take the oath of fraternity of arms with Germany and Austria, Pilsudski was arrested by the Germans and imprisoned with his chief of staff Gen. Sosnowski in the fortress of Magdeburg, whence he was released in 1918 by the German revolutionary authorities. He arrived in Warsaw on Nov. 4 and completed the disarmament of the armies of occupation. The Regency Council established by the Germans resigned in his favour and all military organizations in the country submitted to his command. He was vested with dictatorial powers and elected unanimously chief of State while the army conferred on him the supreme honour of first marshal of Poland.

For Pilsudski's activities during the next years see **POLAND**. His own chief interest was centred in the army, with which he was very popular and at the head of which he undertook the campaigns of 1919 in the Ukraine and against the Russian advance on Warsaw. He had, however, many difficulties with other elements in the State and in 1920 he ceased to be chief of State and retired altogether from the army. In May 1926, however, his notorious dislike of the typically Polish parliamentary wrangling and faction recalled him. He put himself again at the head of the army; a military demonstration on May 12 led to fighting in Warsaw and the resignation of the president. The national assembly convoked by his successor M. Rataj elected Pilsudski president (May 31) but he refused the honour and became only minister of war while his friends MM. Mosiecki and Bartel were elected respectively president and premier. Pilsudski immediately carried through legislation greatly strengthening the position of the president against the parliament but did not dissolve the latter or establish an open dictatorship although he constantly prorogued it. In September, indeed, he took over the premiership himself but seldom appeared in the Sejm even when it was sitting. The elections of March 1928 gave his adherents a majority. Nevertheless Pilsudski, who had been in bad health, resigned the premiership retaining however the ministry of war, chairmanship of the army council and inspectorate general of the force. This change made little difference to his position in Poland and the vigorous abuse of the Sejm with which he motivated his actions was not actively resented. He was again premier in 1930. For the events of his real though veiled dictatorship see **POLAND**. See also R. Landau, *Pilsudski and Poland* (1929).

**PIMA**, a tribe of Indians on Gila and Salt rivers in southern Arizona, closely related to the Papago who adjoin them on the south and to the Pima Bajo in Sonora. They practised irrigation

and lived in permanent though rudely built villages. In their territory are the adobe ruins of Casa Grande and miles of prehistoric ditches. They are divided into five patrilineal totemic groups, make fair pottery and excellent basketry. They differ much from the other sedentary and agricultural natives of the south west, the Pueblos. Consistently friendly to the whites, they long withstood the Apache courageously fought back the hostile Yuman tribes and sheltered those that took refuge with them. Estimated at 2,500 in 1775 they numbered 5,100 in 1911. See F. Russell *Bur Am Ethn Rep* xxvi (1908).

The Piman or Sonoran family now recognized as a division of the larger Uto-Aztecan one, extended from Arizona to Jalisco, Mexico, and included the Pima, Papago, Opatá, Tarahumare, Mayo, Yaqui, Tepehuane, Tepecano, Cora, Huichol and other groups. (A. L. K.)

**PIMPERNEL** (*Anagallis arvensis*) a small herb of the primrose family (Primulaceae) called also shepherd's clock and poor man's weather glass, native to Europe and widely naturalized in North America from Newfoundland to the Pacific coast and southward to Mexico. It is a delicate annual with diffusely branching stems with small opposite somewhat clasping leaves black dotted beneath and scarlet (rarely white) flowers about  $\frac{1}{4}$  in. across, usually with a darker centre opening only in bright sunshine, whence numerous popular names.

**PIN**, a small peg or bolt of metal or wood not necessarily pointed, employed as a fastening to connect together different parts of an article as a stop to limit the motion of some moving piece in a machine as a support on which a small wheel may turn, etc. but most commonly a small metal spike used for fastening portions of fabrics together, having one end pointed and at the other a bulbous head or some other arrangement for preventing the spike from passing entirely through the cloth or other material with which it is employed. In one form or another pins of this last kind are of the highest antiquity, the earliest form doubtless being a natural thorn. Pins of bronze and bronze brooches in which the pin is the essential feature are of common occurrence among the remains of the bronze age. The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France and again in 1543 an act was passed providing that no person shall put to sale any pinnes but only such as shall be double headed and have the heads soldered fast to the shank of the pinnes well smoothed, the shank well shapen, the points well and round filed, canted and sharpened. At that time pins of good quality were made of brass but a large proportion of those against which the legislative enactment was directed were made of iron wire blanché and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626 in which year the manufacture was introduced into Gloucestershire by John Tilsby. In 1636 the pinmakers of London formed a corporation and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native made pins and needles. At a later date several pin making machines were invented in the United States. During the War of 1812 when the price of pins rose enormously the manufacture was actually started but the industry was not fairly successful till about the year 1836 when the Howe Manufacturing company was formed at Birmingham, Connecticut. Previous to this an American, Lemuel W. Wright had in 1824 secured in England a patent for a machine to make solid headed pins which established the industry on its present basis.

**Modern Pin Machinery**—In a modern pin making machine wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws beyond which enough of the end projects to form a pin head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slot sufficient-

ly wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting extremities are held against a revolving cutter by which they are pointed.

Then follows the finishing process which consists of giving the pins the coating of tin which makes them silvery in appearance. In the case of brass pins they are scoured, cleaned in argol (bitartrate of potash) and water and then tinned in a vat in a solution of water, oxalic acid and granulated tin mixed with the pins at a temperature of 100°C. Iron pins are tinned by an electrolytic process in an alkaline solution of a tin salt. After being washed and dried the pins are polished by being revolved in a barrel mixed with dry bran or fine sawdust from which they are winnowed as finished pins. The sizes of ordinary pins range from the  $\frac{3}{8}$  in. stout blanket pin down to the finest slender gilt pin used by entomologists, 4,500 of which weigh about an ounce.

#### PINACEAE see GYMNOSPERMES

**PINACOTHECA**, the Greek name for a picture gallery, apparently reserved in Greece for one that was public although used by the Romans for a picture gallery in a private house. In modern usage the term usually means the chamber forming the left wing of the Propylaea of the Athenian acropolis which was used in ancient times as a picture gallery (Pausanias Bk. II. xxii. 6). Various modern public picture galleries bear the same or a similar name such as those of Bologna and Turin and at Munich the old and the new Pinakothek.

**PINAR DEL RIO**, capital of Pinar del Rio Province, Cuba, about 10 m. SW. by railway from Havana. Pop. (1931) 63,041. The city is in the fertile valley of the Guama. It is the centre of the tobacco industry of the Vuelta Abajo region. Its port is La Coloma on the southern coast. The pueblo was created after 1773 but the history of the settlement goes back to 1571 and the parochial church dates from 1710.

**PINCHBECK** When brass, the familiar alloy of copper and zinc, contains 12% to 15% of the latter metal its colour simulates that of gold. In 1832 a London clockmaker, Christopher Pinchbeck, introduced a brass containing about 15% of zinc for the manufacture of imitation gold jewellery and the yellow metal bore his name, hence the use of the term pinchbeck for flash or imitation jewellery. (See BRASS.)

**PINCHOT, GIFFORD** (1865– ) American forester and public official was born at Simsbury, Conn. on Aug. 11, 1865. He graduated at Yale in 1889 and afterwards studied at the École Nationale Forestière, Nancy, France, and for briefer periods in Switzerland, Germany and Austria. Upon his return he began the first systematic forestry work in the United States in the Vanderbilt forest at Biltmore, N.C. In 1896 he was made a member of the National Forest Commission that worked out the plan of U.S. forest reserves and in 1897 he became confidential forest agent to the secretary of the Interior to examine and report upon the reserves. In 1898 he was appointed chief of the division later the bureau of forestry in the Department of Agriculture which office he held until 1910. During the period of his administration the entire forest system and administrative machinery of the bureau was built up and Pinchot's enthusiasm and publicity work did much for the conservation movement in general. He also served as a member of the committee on public lands, 1903, and the Inland Waterways Commission, 1907. In 1908 he became chairman of the National Conservation Commission and in 1910 president of the National Conservation Association. He founded the Yale School of Forestry at New Haven as well as the Yale Summer School of Forestry at Milford, Pa. and in 1903 became professor of forestry at Yale. He was appointed State forester of Pennsylvania in 1920 and began a systematic administration of the large and important forest areas of that State. From 1923 to 1927 he was governor of Pennsylvania and while in that office forced a reorganization of the State Government and the establishment of a budget system. He was also able in 1923 to settle an important anthracite coal strike by arbitration.

Besides many articles in magazines he has written *The White Pine* (1896), *The Adirondack Spruce* (1898), *A Primer of Forestry* (1899).

*The Fight for Conservation* (1909) *The Training of a Forester* (1917)

**PINCKNEY, CHARLES** (1751-1824) American statesman was born on Oct. 6 1751 at Charleston SC. He was the son of Charles Pinckney (1731-84) first president of the first South Carolina provincial congress (1775) and a cousin of Charles Cotesworth Pinckney and Thomas Pinckney. He was studying law at the outbreak of the Revolutionary War served in the early campaign in the South and in 1779 was elected to the South Carolina house of representatives. He was captured by the British at the fall of Charleston (1780) and remained a prisoner until the close of hostilities. In 1781 he was a delegate to the Federal constitutional convention and on the same day (May 29) on which Edmund Randolph (q.v.) presented what is known as the Virginia plan Pinckney presented a draft of a constitution which is known as the Pinckney plan. Although the Randolph resolutions were made the basis on which the new constitution was framed Pinckney's plan seems to have been much drawn upon. Furthermore Pinckney appears to have made valuable suggestions regarding phrasing and matters of detail. On Aug. 18 he introduced a series of resolutions and to him should probably be accredited the authorship of the substance of some 30 or more provisions of the constitution. Pinckney was president of the State convention of 1790 that framed a new constitution for South Carolina was governor of the State 1789-91 a member of the State house of representatives in 1791-1796 and again governor in 1796-98. From 1799 to 1801 he was a member of the United States Senate. He entered public life as a Federalist but later became the leader in organizing the Democratic Republican party in his State and contributed largely to the success of Thomas Jefferson in the presidential election of 1800. By Jefferson's appointment he was American minister to Spain from 1801 to 1805. In general his mission was a distinct failure his arrogance and indiscretions finally causing the Spanish government to request his recall. He was again governor of South Carolina in 1806-08 and from 1819 to 1821 was a member of the National House of Representatives in which he opposed the Missouri Compromise in a brilliant speech. He died at Charleston SC on Oct. 29 1824.

**PINCKNEY, CHARLES COTESWORTH** (1746-1825) American statesman was born in Charleston SC on Feb. 25 1746 the son of Charles Pinckney (d. 1758) a prominent figure in colonial times by his second wife the celebrated girl planter Eliza Lucas. When a child he was sent to England like his brother Thomas after him to be educated. Both of them were at Westminster and Oxford and were called to the bar and for a time they studied in France at the Royal Military college at Caen. Returning to America in 1769 C. C. Pinckney began the practice of law at Charleston. He was a member of the first South Carolina provincial congress in 1775 served as colonel in the South Carolina militia in 1776-77 was chosen president of the South Carolina senate in 1779 took part in the Georgia expedition and the attack on Savannah in the same year was captured at the fall of Charleston in 1780 and kept in confinement until 1782. He was an influential member of the constitutional convention of 1787 advocating the counting of all slaves as a basis of representation and opposing the abolition of the slave trade. He opposed as impracticable the election of representatives by popular vote and also opposed the payment of senators who he thought should be men of wealth. Subsequently Pinckney bore a prominent part in securing the ratification of the Federal constitution in the South Carolina convention of 1788. In 1796 he succeeded James Monroe as minister to France. The Directory refused to receive him and he retired to Holland but in the next year Elbridge Gerry and John Marshall having been appointed to act with him he again repaired to Paris where he is said to have made the famous reply to a veiled demand for a loan (in reality for a gift) 'Millions for defence but not one cent for tribute'—another version is 'No not a sixpence'. The mission accomplished nothing and Pinckney and Marshall left France in disgust. Gerry (q.v.) remaining. When the correspondence of the commissioners was sent to the United States Congress the letters 'X,' 'Y' and

7 were inserted in place of the names of the French agents with whom the commission treated—hence the X Y Z Correspondence famous in American history. In 1800 he was the Federalist candidate for vice president and in 1804 and again in 1808 for president receiving 4 electoral votes in the former and 47 in the latter year. From 1800 until his death on Aug. 16 1825 he was president general of the Society of the Cincinnati.

**PINCKNEY, THOMAS** (1710-1881) American statesman and diplomat was born in Charleston SC on Oct. 23 1750 a younger brother of Charles Cotesworth Pinckney (q.v.). Educated in England he returned to Charleston in 1773 and was admitted to the bar in 1774. During the American Revolution his military training at the French military college at Caen enabled him to render effective service to Gen. Benjamin Lincoln. Count de Etaing and Gen. Horatio Gates. In the battle of Camden he was badly wounded and captured remaining a prisoner for more than a year. Subsequently he was governor of South Carolina in 1785-89 presided over the State convention which ratified the Federal constitution in 1788 and was United States minister to Great Britain in 1791-96. During part of this time (1794-95) he was also envoy extraordinary to Spain and in this capacity negotiated (1795) the important Treaty of San Lorenzo el Real by that treaty the boundary between the United States and East and West Florida and between the United States and Louisiana was settled (Spain relinquishing all claims east of the Mississippi above 31° N. lat.) and the United States secured the freedom of navigation of the Mississippi to its mouth. In 1796 Pinckney was the Federalist candidate for vice president and in 1797-1801 he was a Federalist representative in Congress. During the War of 1812 he was a major general. He died in Charleston on Nov. 18 1881. The Pinckneys like many other South Carolina revolutionary leaders were of aristocratic birth and politics closely connected with England by ties of blood education and business relations. This renders the more remarkable their attitude in the American Revolution for which they made great sacrifices.

See C. C. Pinckney *Life of General Thomas Pinckney* (Boston 1895).

**PIN-CLOVER** (*Erodium cicutarium*) an annual herb of the geranium family (Geraniaceae) called also hemlock stork's bill and red filaree. It is widespread as a weed in the Old World and is extensively naturalized in North America from Nova Scotia to the Pacific coast being especially abundant from Texas and Colorado westward to California and Oregon where it is highly esteemed as a forage plant. The larger white stemmed pin-clover, musk clover or filaree (*E. moschatum*) native to Europe and locally naturalized in the United States has become very abundant in California valleys.

**PINDAR** (Gr. Πινδαρος, c. 522-443 B.C.) the great lyric poet of ancient Greece was born at Cynoscephalae in Boeotia at the time of the Pythian games (fr. 175 Bergk<sup>4</sup> 193)<sup>1</sup> which is taken by Bockh to be 52 B.C. He would thus be some thirty-four years younger than Simonides of Ceos. He was the son of Daiphantus and Cleodice (or Cleidice). The clan of the Aegidae—tracing their line from the hero Aegeus—belonged to the Cadmean element of Thebes so to the elder nobility whose supposed date went back to the days of the founder Cadmus. Pindar stood that is within the circle of those families for whom the heroic myths were domestic records. He had a personal link with the memories which everywhere were most cherished by Dorians no less than with those which appealed to men of Cadmean or of Achaean stock. And the wide ramifications of the Aegidae throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic.

**Life.**—Pindar is said to have received lessons in flute-playing from one Scopelinos at Thebes and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth as the story went, he was defeated in a poetical contest by the Theban Corinna—who in reference to his profuse employment of Theban mythology, is

<sup>1</sup>The references are to the edition of Pindar by C. A. M. Fennell (1893-99) and the fourth edition of Bergk's *Poetae lyrici graeci*.

said to have advised him to sow with the hand not with the sack. There is an extant fragment in which Corinna reproves another Theban poetess Myrtis for that she a woman contented with Pindar (οὐ βαρὰ φουσ εἶβα Πινδαροιο ποτ' ἐριν) —a sentiment which hardly fits the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was indeed indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music and in the adaptation of both to the intricate movements of the choral dance (ορχηστική).

Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time and at the various elements of art which the lyricist was required to temper into a harmonious whole (see e.g. *Oli* iii 8 vi 91 xiii 18 xiv 15 *Pyth* xii 3 etc.). The earliest ode which can be dated (*Pyth* 1) belongs to the twentieth year of Pindar's age (50 B.C.) the latest (*Olymp* v) to the seventieth (45 B.C.).<sup>1</sup> He visited the court of Hiero at Syracuse. Theron the despot of Agragias also entertained him and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi.

He was greatly honoured by all the Greeks because he was so beloved of Apollo that he even received a share of the offerings and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god.<sup>2</sup> His wife's name was Megacleia (another account says Timoxena but this may have been a second wife) and he had a son named Daiphantus and two daughters Eumetis and Protomache. He is said to have died at Argos at the age of seventy-nine in 445 B.C.

**Piety**—Among the Greeks of his own and later times Pindar was pre-eminently distinguished for his piety towards the gods. He tells us that near to the vestibule of his house (*Pyth* iii 78) choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the phrygian music of the flute in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele which he dedicated at Thebes were the work of the Theban artists Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios and another by Calamis to Zeus Ammon. The latter god claimed his especial veneration because Cyrene one of the homes of his Aegid ancestry stood where Zeus Ammon hath his seat *ie* near the oasis and temple (*Pyth* iv 16). The author of one of the Greek lives of Pindar says that when Pausanias the king of the Lacedaemonians was burning Thebes some one wrote on Pindar's house 'Burn not the house of Pindar the poet and thus it alone escaped destruction. This incident of which the occasion is not further defined has been regarded as a later invention.<sup>3</sup>

Better attested at least is the similar clemency of Alexander the Great when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia or citadel of Thebes (thenceforth to be occupied by a Macedonian garrison) (2) the temples and holy places and (3) Pindar's house. While the inhabitants were sold into slavery exception was made only of (1) priests and priestesses (2) persons who had been connected by private *ξενία* with Philip or Alexander or by public *ξενία* with the Macedonians (3) Pindar's descendants. It is probable enough as Dio Chrysostom suggests (ii 33) that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I of Macedon. But he must have been also or chiefly influenced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods and above all to the Delphian Apollo.

**Praise of Athens**—During the second half of Pindar's life Athens was rising to that supremacy in literature and art which

was to prove more lasting than her political primacy. Pindar did not live to see the Parthenon or to witness the mature triumphs of Sophocles but he knew the sculpture of Calamis and he may have known the masterpieces of Aeschylus. It is interesting to note the feeling of this great Theban poet who stands midway between Homeric epos and Athenian drama towards the Athens of which Thebes was so often the bitterest foe but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those on of Athens who laid the shining foundations of freedom (παιδες Ἀθηναίων ἐβαλοντο φαεινὰν κρητὶς ἐλευθερίας fr 55 Bergk<sup>4</sup> 11) while Athens itself is thus invoked ὦ ται λιπαραὶ καὶ ἰστέφανοι καὶ αἰοιομοὶ Ἑλλάδος εἰρῆσμα ἅλ' ἵται Ἀθαναὶ οἰμονίον πτολιέθρον (fr 54 Bergk<sup>4</sup> 76). Isocrates writing in 355 B.C. states that the phrase Ἑλλάδος εἰρῆσμα stay of Hellas so greatly gratified the Athenians that they conferred on Pindar the high distinction of *προξενία* (*ie* appointed him honorary consul as it were—for Athens at Thebes) besides presenting him with a sum of money (*Antidosis* 166).

One of the letters of the pseudo Aeschines (*Ep* iv) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens and that the Athenians repaid him twice the sum.<sup>4</sup> The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens near the temple of Ares (184). Besides the fragment just mentioned several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars while he gives the glory of Plataea to the Spartans he assigns that of Salamis to the Athenians (*Pyth* 176). In celebrating (*Pyth* vii) the Pythian victory of the Athenian Megacles he begins thus 'Fairest of preludes is the renown of Athens for the mighty race of the Alcmaeonidae. What home or what house could I call mine by a name that should sound more glorious for Hellas to hear?' (Cf also *Nem* v 49).

Pindar's versatility as a lyric poet is one of the characteristics remarked by Horace (*Odes* iv 2) and is proved by the fragments though the poems which have come down entire represent only one class of compositions—the *ἐπνίκια* or odes of victory commemorating successes in the great games. The lyric types to which the fragments belong though it cannot be assumed that the list is complete are at least numerous and varied.

**Fragments**—(1) *ῥυμοὶ* Hymns to deities—as to Zeus Ammon to Persephone to Fortune. The fragmentary *ῥυμος* entitled *Θηβαίους* seems to have celebrated the deities of Thebes (2) *Παιάνες, παεῖς* expressing prayer or praise for the help of a protecting god especially Apollo Artemis or Zeus (3) *Διθύραμβοι* *Dithyrambs* odes of a lofty and impassioned strain sung by choruses in honour of Dionysus (4) *Προσόδια* *Processional Songs* choral chants for worshippers approaching a shrine (5) *Παρθενία* *Choral Songs for Maidens*.

(6) *ὑπορχήματα* *Choral Dance Songs* adapted to a lively movement used from an early date in the cult of Apollo and afterwards in that of other gods especially Dionysus. To this class belongs one of the finest fragments (84 Bergk<sup>4</sup> 107) written for the Thebans in connection with propitiatory rites after an eclipse of the sun probably that of the 30th of April 463 B.C. (7) *Ἐγκωμια* *Songs of Praise* (for men while *ῥυμοὶ* were for gods) to be sung by a festal company (8) *Σκόλια*, *Festal Songs*. The usual sense of *σκόλιον* is a drinking song taken up by one guest after another at a banquet. But Pindar's *σκόλια* were choral and antistrophic. One was to be sung at Corinth by a chorus of the *ιεροδούλοι* attached to the temple of Aphrodite Ourania when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment for Theoxenus of Tenedos has an erotic character.

(9) *Θρήνοι* *Dyges* to be sung with choral dance and the music of the flute either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class.

<sup>4</sup>Compare Jebb *Attic Orators* ii 143

<sup>1</sup>According to others his latest poem is the eighth Pythian ode 450 or 446

<sup>2</sup>Πινδαρου γένος in ed. Ald

<sup>3</sup>A. Schäfer, *Demosthenes und seine Zeit* iii 119

(106-110 Bergk<sup>1</sup> 19-133) A number of small fragments which cannot be certainly classified are usually given as *ἐξ ἀθλῶν εἰσῶν* of uncertain date.

**The Epinicia**—The *ἐπινικία* (*σι μέλη*) or *ἐπινικιοὶ* (*σι ὑμνοὶ*) Odes of Victory form a collection of forty-four odes traditionally divided into four books answering to the four great festivals (1) *Ὀλυμπιονικαὶ* (*σι ὑμνοὶ*) fourteen odes for winners of the wild olive wreath in the Olympian games held at Olympia in honour of Zeus once in four years (2) *Πιθιονικαὶ* twelve odes for winners of the laurel wreath in the Pythian games held at Delphi in honour of Apollo once in four years the third of each Olympiad (3) *Νεμεονικαὶ* eleven odes for winners of the pine wreath in the Nemean games held at Nemea in honour of Zeus once in two years the second and fourth of each Olympiad and (4) *Ισθμιονικαὶ* seven odes for winners of the pine wreath in the Isthmian games held at the Isthmus of Corinth in honour of Poseidon once in two years the first and third of each Olympiad. The Greek way of citing an ode is by the nominative plural followed by the numeral *εἰς* the ninth Olympiad is *Ὀλυμπιονικαῖθ*. The chronological range of the collection (so far as ascertainable) is 50 B.C. (*Pyth* x) to 45 B.C. (*Ol* v).

The general characteristics of the odes may be briefly considered under the following heads: (1) language (2) treatment of theme (3) sentiment—religious moral and political (4) relation to contemporary art.

**Diction**—The diction of Pindar is distinct in character from that of every other Greek poet being almost everywhere marked by the greatest imaginative boldness. Thus (a) metaphor is used even for the expression of common ideas or the translation of familiar phrases as when a cloak is called (*Ol* ix 91) a warm remedy for winds. (b) Images for the highest excellence are drawn from the farthest limits of travel or navigation or from the fairest of natural objects as when the superlative hospitality of a man who kept open house all the year round is described by saying far as to Phasis was his voyage in summer days and in winter to the shores of Nile (*Isthm* ii 41) or when Olympia the crown or flower of festivals is said to be excellent as water bright as gold brilliant as the noonday sun (*Ol* i *ad nut*). This trait might be called the *Pindaric imagery of the superlative*. (c) Poetical inversion of ordinary phrase is frequent as instead of he struck fear into the beasts he gave the beasts to fear (*Pyth* v 56). (d) The efforts of the poet's genius are represented under an extraordinary number of similitudes borrowed from javelin throwing chariot driving leaping rowing sailing ploughing building shooting with the bow sharpening a knife on a whetstone mixing wine in a bowl and many more. (e) Homely images from common life are not rare as from account keeping usury sending merchandise over sea the *σκυτάλη* or secret dispatch etc. And we have such homely proverbs as he hath his foot in this shoe *εἰ* stands in this case (*Ol* vi 8). (f) The natural order of words in a sentence is often boldly deranged while on the other hand the syntax is seldom difficult. (g) Words not found except in Pindar are numerous many of these being compounds which (like *ἐναριμβροτος καταφυλλοροειν* etc.) suited the dactylic metres in their Pindaric combinations. Horace was right in speaking of Pindar's *nova verba* though they were not confined to the audacious dithyrambi.

**Subjects**—The actual victory which gave occasion for the ode is seldom treated at length or in detail—which indeed only exceptional incidents could justify Pindar's method is to take some heroic myth or group of myths connected with the victor's city or family and after a brief prelude to enter on this returning at the close as a rule to the subject of the victor's merit or good fortune and interspersing the whole with moral comment. Thus the fourth Pythian is for Arcesilaus king of Cyrene which was said to have been founded by men of Thera descendants of one of Jason's comrades. Using this link Pindar introduces his splendid narrative of the Argonauts. Many odes again contain shorter mythical episodes—as the birth of Iamus (*Ol* vi) or the vision of Bellerophon (*Ol* xiii)—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical

disposition to his immediate theme. It is bold and swift yet is not felt as harshly abrupt—justifying his own phrase at one such *ἡ γὰρ ταῦτα οἶμον ἱσαμὶ βραχὺ* (*Pyth* ix 41).

**Religious Moral and Political Sentiment**—a The religious feeling of Pindar is strongly marked in the odes. From the gods are all means of human excellence. He will not believe that the gods when they dined with Tanalus ate his son Pelops rather Poseidon carried off the youth of Olympu. This is his reason for rejecting a scandalous story about the odes is purely religious as distinct from moral. It shocks his conception of the divine dignity. With regard to oracles he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood viz that the odes do illumine their prophet but that human wit can foresee nothing, which the gods do no choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (*Ol* ii 60 *seq*). Pindar was familiar with the idea of metempsychosis (cf *ibid* 68) but the attempt to trace Pythagoreanism in some phrases (*Pyth* ii 34 iii 14) appears unsafe. The belief in a fully conscious existence for the soul in a future state determined by the character of the earthly life entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the *Θρηνηος* (114 Bergk<sup>1</sup> 13) we may probably regard the etheric element in Pindar's theology as due to such a source.

b The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (*φύνη*) is the grand source of all human excellence (*ἀρετή*) while such excellences as can be acquired by study (*οὐδαικται ἀρεται* *Ol* ix 100) are of relatively small scope—the sentiment we may remark of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of *ὕγιαιος ὀλβος*—sane happiness such as has least reason to dread the jealousy of the gods—are substance sufficing for daily wants and good repute (*εὐλογία*). He who has these should not seek to be a god. Wealth set with virtues (*πλοῦτος ἀρεταῖς θύοα δαλμενος*) as gold with precious gems is the most fortunate lot because it affords the amplest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said love thy friend and hate thy foe (cf *Pyth* ii 83 *Isthm* iii 65). But in one sense he has a moral elevation which is distinctively his own—he is the glowing prophet of generous emulation and of reverent self control.

c The political sentiments of the Theban poet are suggested by *Pyth* xi 52. In politics I find the middle state crowned with more enduring good therefore praise I not the despot's portion those virtues move my zeal which serve the folk. If in *Pyth* ii 87 a democracy is described as *ὀλαβροσ σπράτος* the raging crowd it is to be noted that the ode is for Hiero of Syracuse and that the phrase clearly refers to the violence of those democratic revolutions which in the early part of the 5th century B.C. more than once convulsed Sicilian cities. At Thebes after the Persian wars a constitutional oligarchy (*ὀλιγαρχία ἰσονομος*, *Thuc* iii 62) had replaced the narrower and less temperate oligarchy of former days (*δυναστεία οὐ μετα νόμων*) and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (*Ol* i 113) he sketches the character of an ideal king (*Pyth* iii 71) but nothing in his poetry implies liking for the *τυραννίς* as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence. He speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours Tranquillity the friend of cities' (*Ἀσυχία φιλοπολὶς* *Ol* iv 16). The epic poet sang of wars Pindar celebrates the rivalries of peace.

**Love of Natural Art.**—Pindar's genius was boldly original at the same time he was an exquisite artist. Mine be it to invent

new strains mine the skill to hold my course in the chariot of the Muses and may courage go with me and power of ample grasp (*Ol ix 80*). Here we see the exulting sense of inborn strength in many other places we perceive the feeling of conscious art—as in the phrase *σαῖδαλαγειν* so apt for his method of inlaying an ode with mythical subjects or when he compare the opening of a song to the front of a stately building (*Ol vi 3*). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears for example in his welcome of the season when the chamber of the hour is opened and delicate plants perceive the fragrant spring (*fr 53 Bergk<sup>4</sup> 15*) in the passage where Jason invokes the rushing strength of waves and winds and the nights and the paths of the deep (*Pyth iv 193*) in the lines on the eclipse of the sun (*fr 84 Bergk<sup>4</sup> 107*) and in the picture of the eruption when Etna pillar of the sky nurse of keen snow all the year sends forth pure springs of fire unapproachable (*Pyth i 10*). The poet's feeling for colour is often noticeable—as in the beautiful story of the birth of Iamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web the babe is found its delicate body steeped in the golden and deep purple rays of pansies (*Ol vi 55*).

**Relation to Art**—The spirit of art in every form is represented for Pindar by *χαρις*—the source of all delights to mortals (*Ol i 30*)—or by the personified Charites (Graces). The Charites were often represented as young maidens decking themselves with early flowers—the rose in particular being sacred to them as well as to Aphrodite. In Pindar's mind as in the old Greek conception from which the worship of the Charites sprang the instinct of beautiful art was inseparable from the sense of natural beauty. The period from 500 to 460 B.C. to which most of Pindar's extant odes belonged marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina were effecting a transition from archaic types to the art which was afterwards matured in the age of Pheidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards sculpture had been applied to the commemoration of athletes chiefly at Olympia.

In a striking passage (*Nem v ad int*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete and contrasts the merely local effect of the statue with the wide diffusion of the poem. No sculptor I to fashion images that shall stand idly on one pedestal for aye no go thou forth from Aegina sweet song of mine on every freighted ship on each light bark. Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian. (2) Hiero's victory in the chariot race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis. (3) the Gigantomachia. (4) the wedding of Heracles and Hebe. (5) the war of the Centaurs with the Lapithae and (6) a contest between Heracles and Apollo are instances of mythical material treated alike by the poet and by sculptors of his day.

**Place in Greek Literature**—In the development of Greek lyric poetry two periods are broadly distinguished. During the first from about 600 to 500 B.C. lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians Alcman and Stesichorus for Dorians. During the second period which takes its rise in the sense of Hellenic unity created by the Persian wars the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period to which Bacchylides the nephew of Simonides also belongs. These with a few minor poets, are classed by German writers as *die universalen Meliker*. The Greeks usually spoke not of lyric but of melic poetry (*melos* meant to be sung and not like the epic recited) and 'universal melic' is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyricist. Epic lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth.

In Pindar we can see that phase of the Greek mind which

produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth ix*) the meeting of Apollo and Chiron (*Pyth ix*) the episode of Caenor and Polydeuces (*Nem x*) the entertainment of Heracles by Telamon (*Isthm v*). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life the Persian invasions they longed to see the heroes moving and to hear them speaking. The poet of Olympia accustomed to see beautiful forms in vivid action or vivid art was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side he has a genuine if less evident kinship with Aeschylus and Sophocles. Pindar's work like Olympia itself illustrates the spiritual unity of Greek art.

The fact that certain glosses and lacunae are common to all our mss of Pindar make it probable that these mss are derived from a common archetype. Now the older scholia on Pindar which appear to have been compiled mainly from the commentaries of Didymus (c. 15 B.C.) sometimes presuppose a purer text than ours. But the compiler of the older scholia lived after Herodian (A.D. 160). The archetype of our mss then cannot have been older than the end of the 2nd century. Our mss fall into two general classes: (1) the older representing a text which though often corrupt is comparatively free from interpolations; (2) the later which exhibit traces of a Byzantine recension in other words of lawless conjecture down to the 14th or 15th century. To the first class belong Parisinus 7 breaking off in *Pyth v* Ambrosianus 1 which has only *Ol i-xii* Mediceus and Vaticanus 2—the two last named being of the highest value. The edition princeps is the Aldine (Venice 1513). A modern study of Pindar may be almost said to have begun with C.G. Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But August Bockh (1811-21) who was assisted in his commentary by L. Dissen is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Birk (*Poetae lyrici graeci* 1878 new ed. by O. Schröder 1900) is marked by considerable boldness of conjecture as that of Tycho Mommsen (1864) by a sometimes excessive adherence to mss. A recension by W. Christ has been published in Teubner series (2nd ed. 1896) also with Prolegomena and commentary (1896) and by O. Schröder (1908). The complete edition of J.W. Donaldson (1841) has many merits but that of C.A.M. Fennell (1879-83 new ed. 1893-99) is better adapted to the needs of English students. The *Olympia* and *Pythia* have been edited by B.L. Gildersleeve (1885) the *Nemaea* and *Isthmia* by J.B. Bury (1890-92) the *Scholia* by E. Abel (1890 unfinished) and A.B. Brachmann (1903). There is a special lexicon by J. Rumpel (1883). The translation into English prose by Ernest Myers (2nd ed. 1883) is excellent. Verse translation by T.C. Baring (1875) and of the *Olympian Odes* by Cyril Mayne (1906) also the edition in the *Loeb Classical Library* with Eng. trans. by J. Sandys (1915). Pindar's metres have been analysed by J.H.H. Schmidt *Die Kunstformen der griechischen Poesie* (Leipzig 1868-72). On Pindar generally see L. Schmidt *Pindar's Leben und Dichtung* (186) F.D. Morice *Pindar* (1879) A. Croiset *La Poésie de Pindare* (1880) G. Lubbert *Pindar's Leben und Dichtungen* (Bonn 1882) W. Christ *Geschichte der griechischen Literatur* (1898) F. Dornseiff *Pindar's Stil* (1921). Bibliographical information on the earlier literature will be found in W. Enselmann *Scriptores graeci* (1881) see also L. Bornemann in *Jahresbericht über die Fortschritt der klassischen Altertumswissenschaft* (ed. C. Bursian vol. cxvi 1904) with special reference to chronological questions and *Pythia i ii iii*. Some considerable fragments of the paeans were discovered in 1906 by B.P. Grenfell and A.S. Hunt see *Paeans in Oxyrhynchus papyri* (pt. v 1908) and A.E. Housman in *Classical Review* (Feb. 1908).

(R.C.J.X)

**PINDARICS**, the name by which was known a class of loose and irregular odes in fashion in England during the close of the 17th and the beginning of the 18th century. The invention is due to Abraham Cowley who probably in Paris and perhaps in 1650 found a text of Pindar and determined to imitate the Greek poetry in English without having comprehended the system upon which Pindar's prosody was built up. Cowley published in 1656 15 *Pindarique Odes* which became the model on which countless imitators founded their pindarics. The erroneous form of these poems which were absolutely without discipline of structure was first exposed by Congreve exactly half a century later. The laxity of these pindarics attracted the poets of the unlyrical close of the 17th century and they served the purpose not only of Dryden and Pope but of a score of lesser poets. Although the vogue of these forms hardly survived the age of Anne something of the vicious tradition of them still remained, and even in the

odes of Word worth Shelley and Coleridge the broken verification of Cowley's pindarics occasionally survives

**PINDARIS**, a word of uncertain origin applied to the irregular horsemen who accompanied the Mahratta armies in India during the 18th century. They received no pay but rather purchased the privilege of plundering on their own account. The majority of them seem to have been Mohammedans. When the regular forces of the Mahrattas had been broken up in the campaigns conducted by Sir Arthur Wellesley and Lord Lake in 1804 the Pindaris made their headquarters in Malwa under the tacit protection of Sindhia and Holkar. They usually assembled annually in November to set forth over British territory in search of plunder. In 1808-9 they plundered Gujarat and in 1811 Mirzapur. In 1814 they were reckoned at 5000 to 30000 horsemen half of them well armed. In 1817 the marquess of Hastings obtained the consent of the East India Company to the organized campaign known as the Pindari War. The Pindaris were surrounded on all sides by a great army consisting of 10000 men and 300 guns and Sindhia overawed was forced to sign the treaty of Gwalior consenting to aid in the extirpation of the Pindaris whom he had hitherto protected. The Peshwa at Poona the Bhonsla raja at Nagpur and the army of the infant Holkar each took up arms but were separately defeated. The Pindaris themselves offered little opposition. Amir Khan their most powerful leader accepted the conditions offered to him. His descendant is now Nawab of the state of Tonk in Rajputana.

See J. Grant Duff *History of the Mahrattas* (186) and Major Ross of Bladensburg, *Marquess of Hastings* (Rulers of India Series) (1893).

**PINDUS**, the ancient name for the mountains which separate Thessaly from Epirus often used by modern geographers in a somewhat extended sense. The folded Alpine chains are continued down the western coast of the Balkan peninsula where in the north they form the Dinaric Alps. In the neighbourhood of Scutari (Skadar) however the direction of the coast line undergoes a marked change associated with a change in the trend of the mountain folds. In the extended sense the name Pindus is applied to the chain of fold mountains which extends from the Sar Plamina in the latitude of Scutari southwards to about the latitude of the Gulf of Arta and thus includes most of the mountains of Albania. As a rule massive limestones are less developed in the Pindus than in the Dinaric region so that the karstic type of landscape is less frequent and less repellent than in the north the prevailing types of rocks being often schists, grits and greenish eruptive rocks especially serpentines. The range rises to a maximum height of about 8000 feet and in places the original forests mainly of oak and beech have been preserved.

**PINE**, a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied and as limited by modern botanists the designation of a large genus (*Pinus*) of true conifers differing from the firs in their hard woody cone scales being thickened at the apex and in their slender needle-shaped leaves growing from a membranous sheath either in pairs or from three to five together—each tuft representing an abortive branch springing from the axil of a partially deciduous scale leaf the base of which remains closely adherent to the stem. The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots the anther scales surmounted by a crest-like appendage shed their abundant pollen by longitudinal slits the two ovules at the base of the inner side of each fertile cone scale develop into a pair of winged seeds which drop from the opening scales when mature.

The pines which comprise about 70 species are widely distributed over the north temperate zone in the southern portions chiefly confined to the mountains along which in Central America a few are found within the Tropics in more northern regions they frequently form extensive forests sometimes hardly mingled with other trees. One species occurs native in Great Britain about 30 are indigenous to the United States and Canada. Their soft straight grained resinous and often durable wood gives to many kinds a high economic value and some are among the most esteemed of timber trees.

Of the two leaved species *P. sylvestris* the pine of northern Europe may be taken as a type. When growing in perfection it is one of the finest of the group and perhaps the most picturesque of forest trees attaining a height of from 50 to 100 ft. It is of conical growth when young but in maturity acquires a spreading cedar or mulberry-like top with a straight trunk two to four feet in diameter at the base and gnarled twisted boughs densely

SCOTCH FIR (*PINUS SYLVESTRIS*)  
B h with mal fl w ab e  
y g c n b l w (A) winged

clothed at the extremities with glaucous green foliage which contrasts strongly with the fiery red brown bark. The leaves are rather short curved and often twisted the male catkins in dense cylindrical whorls fill the air of the forest with their sulphur-like pollen in May or June and pollinate the purple female flowers which at first sessile and erect then become recurved on a lengthening stalk the ovate cones about the length of the leaves are not fertilized until the next summer and do not reach maturity until the autumn of the following year. They seldom open and scatter their seeds until the third year. *P. sylvestris* is found in greater or less abundance from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest slopes of Etna while in longitude its range extends from the shores of the North Sea to Kamchatka. Nowhere more abundant than in the Scandinavian peninsula this tree is the true fir (*fur fura*) of the old Norsemen and still retains the name in Great Britain though botanically now classed as a pine. It grows vigorously in Lapland on the lower ground while in south Norway it occurs up to 3000 ft though the great forests from which Norway pine timber is chiefly derived are on the comparatively lower slopes of the south eastern dales in the highest situations it dwindles to a mere bush. It furnishes the yellow deal of the Baltic and Norway. In Germany both on the mountains and the sandy plains woods of kiefer are frequent and widely spread while vast forests in Russia and Poland are chiefly composed of this species in many northern habitats it is associated with the spruce and birch. In Asia it abounds in Siberia and on the mountains of the Amur region on the European Alps it occurs at a height of 5600 ft and on the Pyrenees it is found at still higher elevations. In Great Britain natural forests of Scotch fir of any extent are only now found in the Highlands chiefly on the declivities of the Grampians. The tree is not at present indigenous in southern Britain but when planted in suitable ground multiplies rapidly by the wind sown seeds on many of the sandy moors and commons natural pine woods of large extent have been thus formed during recent years. The heartwood of the finer kinds of Scotch fir is of a deep brownish red colour abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak and for ship planking is perhaps little inferior from its lightness and elasticity it is well adapted for the construction of yachts and other small fast sailing craft and is said to be the best of all wood for masts and large spars its weight varies from 30 to 40 lb per cubic foot. Great numbers of young pines are annually cut for railway sleepers mining timber and numerous agricultural applications large quantities are consumed for wood pavement. The quality of the timber depends greatly on the soil and position in which the trees are grown. The rapidity of growth is still more variable in Britain full maturity is attained in from 70 to 120 years but in Norway the trunk increases much more slowly. Schubeler states that a tree felled in the Alten district (about 70 lat) measuring 2 ft 10 in in diameter showed 400 annual rings.

In the economy of the northern nations of Europe *P. sylvestris* is an important tree. In Scandinavia and Russia houses are chiefly constructed of its timber and log huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes and in times of scarcity is kiln dried ground up and mixed with meal.

Vast numbers of Scotch firs are raised in nurseries for artificial planting. The seed is sown in the spring being just covered with earth and the seedlings transplanted in the second year into rows for further culture or taken direct to the seed bed for final planting. Sometimes the seed is sown where the trees are intended to grow. A plantation of young Scotch firs requires frequent and careful thinning as the young trees increase in size but pruning should be avoided as much as possible except for the removal of dead wood.

In Great Britain *P. sylvestris* is subject to many insect depredations. The pine chafer *Hylurgus pimplerda* is destructive in some places. The larva of this beetle feeding on the young succulent shoots especially in young plantations. The fir weevil *Hyllobius abietis* eats away the bark and numerous lepidopterous larvae devour the leaves. The pine sawfly is also injurious in some seasons. The removal of all dead branches from the trees and from the ground beneath them is recommended as most of these insects lay their eggs in the decaying parts of the bark and among the dead leaves.

In common with other pines *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem causing rotting of the wood. The disease is difficult to eradicate as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus* which spreads in the soil by means of its long purple black cord like mycelial strands known as *Rhizomorpha*. Much damage is often caused by species of *Peridermium* which often invade the soft portions of the inner bark to such an extent as to ring the stem or branch or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water. This causes the parts above the diseased area to perish.

Plantations in England are generally ready for final cutting in from 60 to 70 years and many are cleared at a much earlier stage of growth especially when protected from injury by pests. In England the pine is largely employed as a nurse for oak trees its conical growth when young admirably adapting it for this purpose. Its dense foliage renders it valuable as a shelter tree for protecting land from the wind. It stands the sea gales better than most conifers but will not flourish on the shore like some other species. This pine is planted for ornament in the Eastern United States where it has become sparingly naturalized. It has also proved of value in afforesting treeless lands as in the National forest in western Nebraska.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark terminating below in a deep notch cut in the wood into which the turpentine runs and from which it is scooped as it accumulates but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris* it is chiefly obtained from the roots.

Closely allied to the Scotch pine and perhaps to be regarded as a mere alpine form of that species is the dwarf *P. Pumilio* the krummholz or knieholz of the Germans—a recumbent bush generally only a few feet high but with long zigzag stems that root occasionally at the knee like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir but is shorter denser and more rigid. The cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tyrolean Alps it is a favourite shelter for the chamois the hunters call it the latschen from its recumbent straggling habit.

The red pine *P. resinosa* of south-eastern Canada and the northern border of the United States from Minnesota eastward (so called from the colour of its bark) is a tree sometimes 120 ft high with a trunk 3 ft or more in diameter. The somewhat glaucous leaves form dense tufts at the ends of the branches and are

4 or 5 in long. The ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous but it is less durable than Scotch fir although much employed in ship building.

*P. Laricio* the Corsican pine is one of the noblest trees of this group growing to a height of 100 or even 150 ft with a straight trunk and branches in regular whorls forming in large trees a pyramidal head. The slender leaves of a dark green tint are from 4 to 7 in long. The cones either in pairs or several together project horizontally and are of a light brown colour. This pine abounds in Corsica and is found in more or less abundance in Spain southern France Greece and many Mediterranean countries. The tree is of very rapid growth but produces good timber much used in southern dockyards and very durable though less strong than that of *P. sylvestris*. The heart wood is of a brownish tint. In southern France it has been planted with success on the drift sands of the Bay of Biscay though it does not bear the full force of the sea blast as well as the pinaster. In England it grows well in sheltered situations and well drained soils. The black pine *P. austriaca* generally now regarded as a variety of *P. Laricio* derives its name from the extreme depth of its foliage tints—the sharp rigid rather long leaves of a dark green hue giving a sombre aspect to the tree.

*P. Pinaster* the cluster of pinaster is an important species from its vigorous growth in the sand drifts of the coast for the purpose of binding which it has been grown more extensively and successfully than any other tree especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft the deeply furrowed trunk occasionally reaches a diameter of 3 ft or more at the base where like most sand trees it usually curves upward gradually a form that enables the long tap roots to withstand better the strain of the sea gale. When once established the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem with their thick covering of long dark green leaves giving a massive rounded outline to the tree. The ovate cones are from 4 to 6 in long of a light shining brown hue with thick scales terminating in a pyramidal apex. They are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift sands of France especially in the Gironde forests have been formed mainly of this pine. The seeds sown at first under proper shelter and protected by a thick growth of broom sown simultaneously vegetate rapidly in the sea sand and the trees thus raised have by their wind drifted seed covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster apart from the production of timber in a once treeless district have a great economic value as a source of turpentine. In England the cluster pine has been largely planted on sandy districts near the sea and has become naturalized in Purbeck and other wild tracts in the southern counties.

*P. Pinea* is the stone pine of Italy its spreading rounded canopy of light green foliage supported on a tall and often branchless trunk forms a striking feature of the landscape in that country as well as in some other Mediterranean lands. The beautiful reddish brown shining cones roundly ovate in shape with pyramidal scale apices have been prized from the ancient days of Rome for their edible nut like seeds (pignons) which are still used as an article of food or dessert. They do not ripen until the fourth year and are kept in the cone until required as their abundant oil soon turns rancid.

Nearly approaching this is *P. excelsa*, the Bhotan or blue pine which differs chiefly in its longer cones and drooping glaucous foliage. It is found in Kumaon and Bhotan and on some of the Nepal ranges but does not grow in the moist climate of the Sikkim Himalayas. It is found at a height of 7 000 to 12 000 ft and attains large dimensions.

*P. Cembra* is the stone pine of Siberia and central Europe. It abounds on the Alps the Carpathians and the Siberian ranges in Switzerland being found at an altitude of 4 000 to 6 000 ft. The seeds are only like those of *P. Pinea* and are eaten both on the Alps and by the inhabitants of Siberia. A fine oil is expressed

from them which is used both for food and in lamp. The growth of *P. Cembra* is slow but the wood is of remarkably even grain and is employed by the Swiss wood carver in preference to any other. Numerous species of pine are planted for ornamental afforestation and timber production.

**North American Pines.**—The 33 or more species and major varieties of pine native to North America north of Mexico may be grouped in two sections the *soft pines* and the *pitch pines*.

The *soft pines* have soft close grained wood with thin nearly white sapwood the sheaths of the leaf clusters fall off early (deciduous) the leaves contain a single fibrovascular bundle and excepting those of the nut pines the leaves are in five leaved clusters.

There are 11 species only one of which the eastern white pine is found east of the Great Plains the others occurring in the Rocky Mountain region and on the Pacific coast.

The soft pines consist of four groups (1) the *white pines* large trees with long stalked thin scaled cylindrical cones including the eastern white pine (*P. Strobus*) the western white pine (*P. monticola*) and the sugar pine (*P. Lambertiana*) (2) the *stone pines* medium sized trees with short stalked thick scaled cones including the lamber pine (*P. flexilis*) and the whitebark pine (*P. albicaulis*) (3) the *foxtail pines* rather small trees with short stalked ovoid prickly cones including the foxtail pine (*P. Balfouriana*) and the bristle cone pine (*P. aristata*) and (4) the *nut pines* small trees with leaves in one to four leaved clusters globose cones and large edible seeds including the pinon (*P. edulis*) the single leaf pinon (*P. monophylla*) the Parry pinon (*P. Parryana*) and the Mexican pinon (*P. cembroides*). By some authorities *P. edulis*, *P. monophylla* and *P. Parryana* are regarded as varieties of *P. cembroides*.

The eastern white pine *P. Strobus* known also as Weymouth pine because of its large growth and soft even grain of its white wood is one of the most valuable of North American timber trees. It once formed extensive forests from Newfoundland to Manitoba and along the northern border of the United States from Maine to Minnesota and also southward in the mountains to Georgia but it has been so long sought for by the lumberer that most of the old trees have long disappeared. On a deep rich soil *P. Strobus* sometimes attains a height of 100 ft and a trunk diameter of 4 to 6 feet. The wood of the white pine is durable for indoor use especially when protected by paint its smooth easily worked grain rendering it a favourite wood for the house carpenter and joiner. The western white pine *P. monticola* a mountain species of the north western United States and British Columbia with light brown wood is extensively cut for lumber especially in Idaho.

The sugar pine or giant pine *P. Lambertiana* of California the largest of known pines rises to a height of 100 ft to 120 ft with a trunk from 6 ft to 8 ft or occasionally 1 ft in diameter. The head is of a pyramidal form the lower branches drooping like those of a Norway spruce its foliage is of a light bright green colour. The pendent cones are very large sometimes 18 in long and 4 in in diameter with large nut like seeds which pounded and baked are eaten by the Indians. It is lumbered extensively the wood being highly valued for indoor carpentry.

The *pitch pines* have usually heavy coarse grained mostly dark coloured wood with pale often thick sapwood the sheaths of the leaf clusters are persistent (except in the Chihuahuana pine) the leaves have two fibrovascular bundles and are arranged mostly in three leaved and two leaved clusters. There are some 4 species about equally divided in number between the region east of the Great Plains and the region extending from the Rocky Mountains to the Pacific coast.

The group of pitch pines with the leaves usually in three leaved clusters includes several of the most valuable trees of North America. Among these are the longleaf pine (*P. palustris*) the slash pine (*P. caribaea*) the loblolly pine (*P. Taeda*) the pitch pine (*P. rigida*) and the pond pine (*P. serotina*) of the southern States and the western yellow pine (*P. ponderosa*) the Jeffrey pine (*P. Jeffreyi*) and the Arizona pine (*P. arizonica*) of the Pacific States. Other representatives of the three leaved group are

the Monterey pine (*P. radiata*) the knob cone pine (*P. attenuata*) the digger pine (*P. Sabiana*) and the Coulter pine (*P. Coulteri*) of California and Oregon and also the Chihuahuana pine (*P. muhlenbergii*) on the Mexican border.

The group of pitch pines with leaves usually in two leaved clusters also comprises several important trees. Among these are the red or Norway pine (*P. resinosa*) the grey or jack pine (*P. Banksiana*) the spruce pine (*P. glabra*) the shortleaf pine (*P. echinata*) the Virginia pine (*P. virginiana*) the sand pine (*P. clausa*) and the mountain pine (*P. pungens*) of the region east of the Rocky Mountains. Here belong also the lodge pole pine (*P. contorta*) found from N. Mexico to Alaska and the knob cone pine (*P. attenuata*) of California and Oregon. Other representative of the two leaved group are the bishop pine (*P. muricata*) and the rare Torrey pine (*P. Torreyana*) both confined to the California coast.

Long leaf pine (*P. palustris*) is the Georgia pitch pine or yellow pine of the southern States it abounds on sandy soils from the Carolinas and Florida westward to Louisiana and Texas. The most marked feature of the tree is its long tufted foliage—the leaves of a bright green tint springing from long white sheaths being often a foot in length. The tall columnar trunk sometimes 100 ft high furnishes one of the most valued pine timbers of the United States close grained and resinous it is very durable and holdshe well it is largely employed in construction work and large quantities are exported especially to Great Britain and the West India. This tree is the chief lumber producing pine of the southern United States it also yields large quantities of tar and turpentine.

The loblolly pine *P. Taeda* a tall tree with straight trunk and spreading top covers great tracts of the pine barrens of the southern States but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming hence the woodsmen call it the old field pine while from the fragrance of its abundant resin it is also known as the frankincense pine. It is a fine species 80 to 100 ft high having sometime a girth of 6 or 8 ft. The timber of this pine though soft and brittle is much used for lumber and the forests of it are of importance because of the turpentine they yield.

The western yellow pine or bull pine *P. ponderosa* which grows from 150 ft to 200 ft high with a massive trunk 5 ft to 8 ft in diameter is noted for the extreme density of its wood which barely floats in water it is the most widely distributed pine tree of the mountain forests of western North America from British Columbia to South Dakota (Black Hills) and south to Texas and Mexico. It is the chief lumber pine of the Pacific States where it is second in importance only to the Douglas fir (*Q. v.*). The Coulter pine *P. Coulteri* is remarkable for its enormous cones (sometimes a foot long 6 in in diameter and weighing more than 4 lb) the scales end in long hooked points curving upwards the leaves are long rigid and glaucous in hue. Nearly related to this is the digger pine *P. Sabiana* of California the cones of which are 7 to 9 in long and 5 to 6 in in diameter also with hooked scales the large nut like seeds are eaten by the Indians the tree sometimes attains a height of 80 ft and a trunk diameter of 4 feet. The beautiful Monterey pine *P. radiata* found sparingly along the California coast is distinguished by the brilliant colour of its foliage. The Torrey pine *P. Torreyana* with leaves 12 in long found only in a narrow strip some 8 m in length along the coast near San Diego Calif and on Santa Barbara island is the least widely distributed of all known pines.

The pitch pine *P. rigida* found from the coast of Massachusetts south westward throughout the Appalachian region is a tree of from 40 to 50 ft in height with rugged trunk occasionally 3 ft in diameter the short dark green leaves are in thick tufts contrasting with the pale yellowish usually clustered cones the scales of which are furnished with small curved spines. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt marshes.

**Pine Lumbering in the United States.**—The various native species of pine several of which form forests of vast extent constitute the chief source of the soft wood (coniferous) lumber

produced in the United States. According to the census of manufactures the total cut in 1935 of both soft wood and hard wood lumber was 383,861,400 bd ft. This had an aggregate value at the mill of \$104,480,000. Of this total there was cut from pine trees an aggregate of 18,191,840,000 bd ft. valued at the mill at \$500,660,114. The pine forests of the country therefore contributed 4.5% of the footage and 46.6% of the value of all lumber produced. For the same year the total cut of soft wood lumber was 31,686,919,000 bd ft. which had a mill value of \$824,342,161. Toward these totals pine lumber furnished 51.1% of the footage and comprised 60.1% of the mill value. Further details confirming the pre-eminence of pine timber in the soft wood lumber industry of the country are shown in the accompanying table.

Production of Soft wood (Coniferous) Lumber in the United States 1925

Name of Wood	Production Board Feet	Av Value at Mill per M bd ft \$	Total Value \$	% of U S Total Value
<i>Pines</i>				
Yellow Pine	18,216,630,000	7.48	500,660,114	60.7
Western Yellow Pine	13,235,936,000	26.46	350,248,806	42.9
White Pine	3,127,208,000	1.70	86,635,66	10.3
Sugar Pine	1,521,128,000	32.58	49,558,830	6.0
Lodge pole Pine	306,992,000	44.79	13,750,162	1.6
	24,979,000	20.22	505,074	0.06
<i>Other Conifers</i>				
Douglas Fir	13,495,635,000	23.98	323,682,047	39.3
Hemlock	8,154,375,000	20.94	171,752,571	20.8
Cypress	2,139,631,000	21.58	46,173,236	5.6
Redwood	90,590,000	40.90	36,915,931	4.5
Spruce	510,639,000	33.99	20,404,54	2.5
Cedar	751,600,000	27.98	20,269,426	2.5
White Fir	372,162,000	38.80	14,439,886	1.8
Larch	356,887,000	22.51	7,583,326	0.9
(Tamarack)				
Palsam Fir	306,991,000	18.25	5,605,86	0.7
Total Soft Woods (Conifers)	19,686,000	26.65	521,631	0.06
	31,711,898,000	25.99	824,342,161	100.0

If the immense footage cut from the Douglas fir (*q.v.*) commonly known to a large part of the lumber trade as Oregon or western pine is added to that produced from the true pines then the total footage marketed as pine lumber amounted in 1925 to 26,356,657,000 bd ft. with a mill value of \$672,412,685 or 68.8% of the footage and 6.6% of the mill value of all lumber manufactured in the United States.

Commercially the lumber cut from the various kinds of pine is known as *white yellow western yellow sugar and lodge pole* pine and is classified under these descriptive names in the census of manufactures. White pine lumber includes that produced from the eastern white or Weymouth pine the western white pine the grey or jack pine and the Norway or red pine the two last named belonging botanically with the yellow pines. Prior to 1900 the eastern white pine was one of the chief lumber producing trees in America but the original forests have become so depleted that the tree now contributes only a minor fraction of the lumber marketed as white pine. The lumber from the eastern white the grey and the red pine is mostly cut in the northern border States from Maine to Minnesota. Western white pine lumber is practically all produced in Idaho (389,267,000 bd ft.) and Washington (90,559,000 bd ft.).

Yellow pine lumber is cut mainly in the southern States 70% of the total is produced in five States: Mississippi, Louisiana, Alabama, Texas and Georgia which rank in the order named. The kinds of pine furnishing yellow pine lumber all belong to the pitch pine group and include the longleaf loblolly shortleaf sand slash pitch spruce pond mountain and Virginia pine the long leaf shortleaf loblolly and slash pines ranking among the most important.

Western yellow pine lumber practically all cut from *P. ponderosa*, is produced chiefly in Oregon 32% California 25% Washington, 14% and Idaho 12%.

Sugar pine lumber cut from a single species (*P. Lambertiana*) and produced commercially only in California (97.5%) and Oregon (2.5%) in 1935 commanded the highest average price at the mill of any pine lumber cut in the United States. Lodge pole pine lumber is produced in small quantities in the Rocky Mountain State—Wyoming contributing 48% Colorado 42% Montana 5% and Utah 4% of the total footage. See UNITED STATES *Fauna and Flora* Plate VII and the map showing forest distribution.

For further details see A. Engler and K. Prantl *Die natürlichen Pflanzenfamilien* (188–1908) A. Veitch *Manual of the Coniferae* (1915) C. S. Sargent *Manual of the Trees of North America* (1905 2nd ed. 1935) L. H. Bailey *Manual of Cultivated Plants* (1924) G. B. Sudworth *Check List of the Forest Trees of the United States* U. S. Dept. Agr. Misc. Pub. 92 (1927).

**PINE APPLE** The pine apple so called consists in reality of the inflorescence of the plant the originally separate flowers of which together with the bracts supporting them become fleshy and consolidated into one mass. The swelling and fusion of the tissues take place after the process of fertilization and it may be that the richly perfumed succulent mass is an aid in the distribution of seed by affording food to certain animals. In the highly developed cultivated pines however it frequently happens that the seeds do not ripen properly. The pine apple *Ananas sativus* is a member of the family Bromeliaceae of tropical American origin where it is widely spread and it is now naturalized in the tropical regions of the Old World. It is cultivated on an extensive commercial scale in the Hawaiian Islands.

Evelyn in his *Diary* mentions tasting a pine apple from Barbados at the table of Charles II. and this is we believe the first mention of the fruit in English literature. For many years pine apples

PINE APPLE (*ANANAS SATIVUS*) FROM A MODERN PHOTOGRAPH OF PINE APPLES GROWING IN THE OPEN

were cultivated in large private gardens but owing to the great developments in the West Indies etc. they are no longer grown in Britain or Europe.

**PINE BEETLE**, the name applied to several beetles (see COLEOPTERA) that attack pines and other coniferous trees particularly in North America. The most important of these are *Dendroctonus ponderosa* which has done great damage to the timber of the Black Hills forest reserve it attacks the main trunk of the tree. The wood engraver bark beetle (*Xyleborus coelatus*) attacks the white and yellow pines (*Pinus strobus* and *P. palustris*) while *X. pubescens* feeds on *P. mops*. All these beetles belong to the bark boring family Scolytidae (see COLEOPTERA ENTOMOLOGICAL Economic).

**PINE BLUFF**, a city of Arkansas, USA, 45 m SSE of Little Rock on the south bank of the Arkansas river at an altitude of 15 ft. county seat of Jefferson county. It is served by the Missouri Pacific and the St. Louis Southwestern railways and has a municipal airport of 224 ac. 15 m north of the city. Pop. (1920) 19,280 (33% negroes) in 1930 20,760 by the Federal census. The city stands on bluffs overlooking the river. It is the seat of the State industrial school for boys and of the Agri-

cultural Mechanical and Normal school for negroes (opened 1875) a branch of the State university Its whole manufacturing business covers most of southern Arkansas and parts of Texas Louisiana and Mississippi Its manufactures were valued at \$1,605,404 and include sawmills hops lumber mill and woodworking plants and factories making locomotives and car castings brake shoes automobile bodies and top mixed feeds cotton yarn and knit underwear The cotton exchange handles 1,500,000 bales in a normal year of which 400,000 are bales (of strong fibre and average in length) which are grown in Jefferson county There is an ample supply of natural gas and hydro electric current The city is assessed for 1917 was \$1,856,830 Bank deposit on June 30, 1917 aggregated \$1,366,666 Pine Bluff was laid out in 1835 and chartered as a city in 1885

**PINEHURST**, a winter resort in the long leaf pine region of the sandhills belt of North Carolina U S A 15 mi southwest of Raleigh on Federal highway 15 and the Norfolk and Southern railroad 550 ft above sea level The 1930 census gives the resident population as 1,035 and the number of visitors averages about 10,000 through the season (October to May) Pinehurst was established by the late James W Tufts Boston soda fountain manufacturer who purchased 5,000 ac of cut over timber land from the late Ambassador to England Walter Hines Page and his brothers Mr Frederick Law Olmsted made the original landscape plan and the town is famous for its winding shrubbery bordered roads and atmosphere of a small New England country village It is the leading winter resort for golf the Pinehurst Country Club having four 18 hole courses all laid out by Donald Ross the championship course being rated by professionals as one of the best in the country Except for the national championships the club's annual North and South golf tournaments are the oldest established amateur and professional events in America Pinehurst is recognized as providing ideal winter conditions for horses Aside from the many private riding horses brought down each fall by horse lovers harness horses sledgechasers and some runners and show horses are wintered and trained here There is an excellent airport near Pinehurst and a modern hospital The village is well equipped there being both a public and a private school a modern moving picture theatre ample store and shopping facilities a model dairy a greenhouse fireproof garage library etc There is a non sectarian church for winter visitors known as the Village Chapel a Catholic church and a non sectarian Community church for the permanent residents Many fine winter homes have been built in and around the village and most of these are occupied for the full six months of the season Pinehurst is not incorporated as a municipality the utilities as well as the principal hotels being owned and operated by Pinehurst Incorporated

**PINEL, PHILIPPE** (1745-1866) French physician was born at Saint Andre Tarn France on April 20 1745 He took his doctor's degree at Toulouse in 1773 His first publication was a French translation of William Cullen's *Nosology* (1785) it was followed by an edition of the works of G Baglivi (1788) and in 1791 he published a *Traite medico philosophique sur l'alienation mentale* in which he advocated a more humane treatment of the insane It is on this advocacy and on the practical effect he was able to give to his ideas that his fame rests His opportunity came with his appointment in 1791 as head physician of the Bicêtre and two years afterwards of the Salpêtrière His chemical lectures at the Salpêtrière formed the basis of his *Nosographie philosophique* (1798) which was further developed in *La Médecine clinique* (1802) Pinel was made a member of the Institute in 1803 and soon afterwards was appointed professor of pathology in the École de Médecine He died at Paris on Oct 26 1826

See notices by E Pariset and Esquirol in *Mémoires de l'Académie de Médecine* (1828)

**PINE-NUT or PINON** see NUT

**PINERO, SIR ARTHUR WING** (1855-1934) English dramatist was born in London on May 24 1855 the son of John Daniel Pinero a Jewish solicitor whose family was of Portuguese origin long established in London A W Pinero was engaged in 1874 as an actor at the Theatre Royal Edinburgh and came to

London in 1876 to play at the Globe theatre Later in the year he joined the Lyceum company of which he remained a member for five years The first piece of his to see the footlights was *Lothair* played in Oct 1877 at the Globe theatre for the benefit of F H M Allen

The first play to make a hit was *The Money Spinner* (Theatre Royal Manchester Nov 1881) but in *The Squar* (St James's Theatre Dec 1883) he attracted serious attention and gave promise of the qualities of his later work In 1885 and 1884 Pinero produced seven pieces but the most important of his works at this period were the successful farces produced at the Court theatre *The Magistrate* (March 1885) which ran for more than a year *The Schoolmistress* (March 1886) *Dandy Dick* (Jan 1887) revived in February 1900 *The Cretin* (Jan 1890) and *The Imitations* (March 1895) Two comedies of sentiment *Sweet Land* (Terry's March 1888) and *The Weather* (Theatre Royal Manchester Sept 1888) met with success and *Sweet Land* has enjoyed numerous revivals With *The Profligate* (Garrick April 1889) he returned to the serious drama

*The Second Mrs Tanqueray* (St James's May 7 1893) dealt with the concrete of the question propounded in *The Profligate* but with more art and more courage The piece aroused great discussion and placed Pinero in the front rank of living English dramatists It was translated into French German and Italian and the part of Paula Tanqueray created in the first place by Mrs Patrick Campbell attracted many actresses among others Elconora Duse His later plays include *The Notorious Mrs Ebb Smith* (1895) *The Benefit of the Doubt* (1895) *The Princess and the Butterfly* (1897) *Trelawney of the Wells* (1898) *The Gay Lord Quex* (1899) *Iris* (1901) *Letty* (1903) *A Wife With out a Smile* (1904) *His House in Order* (1906) *The Thunderbolt* (1908) *Mid Channel* (1909) *The Big Drum* (1915) and *The Enchanted Cottage* (1917) Pinero was knighted in 1909

His *Plays* (11 vols 1891-1895) have prefaces by M C Salaman See also H Hamilton Fyfe *A W Pinero* (1907)

**PINEROLO**, city and episcopal see of Piedmont Italy in the province of Turin Pop (1931) 16,099 (town) 2,890 (commune) It is built on a hill side just above the valleys of the Chisone and the Lemina at a height of 1,344 ft above the sea 4 m by rail SW of Turin Till 1696 it possessed a citadel regarded as the key of Italy in which Fouquet De Caumont Lauzun and the man with the iron mask were imprisoned

**PIN-EYED**, a botanical term for flowers which occur in two forms one of which show the stigma at the mouth of the corolla as in the primrose The term is contrasted with thrum eyed where instead of a single stigma a ring of five stamens is visible

**PING PONG**, see TABLE TENNIS

**PINK**, in botany the common name for a numerous genus (*Dianthus*) of the pink family (Caryophyllaceae *q v*) There are about 250 species natives of the Old World but found chiefly in the Mediterranean region They are herbaceous perennials of low stature often with very showy flowers Four species grow wild in Great Britain the Deptford pink (*D Armeria*) the maiden pink (*D deltoides*) the Cheddar pink (*D caesus*) and the proliferous pink (*D prolifer*) Two others the garden pink (*D plumarius*) and the clove pink or carnation (*D Caryophyllus*) are more or less naturalized in Great Britain The carnation (*q v*) and picotee are modifications of the clove pink a native of Europe These by the old writers were called gilly flowers The sweet william of the gardens is derived from *D barbatus* native to Europe and Asia

The sea pink or thrift *Armeria vulgaris* is a member of the family Plumbaginaceae found on sea shores and mountains

**PINKERTON, ALLAN** (1819-1884) American detective was born in Glasgow Scotland Aug 25 1819 In 1842 he emigrated to Chicago Ill and in 1843 he removed to Dundee Kane county Ill Here he ran down a gang of counterfeiters and was therefore appointed a deputy sheriff of Kane county in 1846 and immediately afterwards of Cook county with headquarters in Chicago There he organized a force of detectives to capture thieves who were stealing railway property This organization developed in 1852 into Pinkerton's National Detective Agency,

since well known for its activities in industrial disputes etc. Some of his notable successes were the capture of the principals in the theft of \$700,000 from Adams Express Company in 1866 and the uncovering of a plot to assassinate President Elect Lincoln in February 1861 when he arrived in Baltimore on his way to Washington. In 1861 Pinkerton organized a system of obtaining military information in the Southern States and from this system he developed the Federal secret service. One of his detectives James McParlan from 1815 to 1816 lived among the Molly Maguires (qv) in Pennsylvania and secured evidence which led to the breaking up of the organization. Pinkerton died in Chicago on July 1, 1884. He published *The Molly Maguires and the Detectives* (1811), *The Spy of the Rebellion* (1883), in which he gave his version of President elect Lincoln's journey to Washington and *Thirty Years a Detective* (1884).

**PINKNEY, WILLIAM** (1764-1822) American lawyer and statesman was born in Annapolis Md. on March 1, 1764. He was admitted to the bar in 1786 and from 1788 to 1799 practiced in Harford county. In 1788 he was a member of the State convention which ratified the Federal Constitution for Maryland (1788-9) and in 1795 of the house of delegates (where in 1788 and 1789 he defended the right of slave owners to free their slaves) and from 1790 to 1795 of the State executive council. From 1796 to 1804 he was commissioner to England to determine the claims of American merchants under the Jay Treaty of 1794 and adjusted a claim of \$800,000 for Maryland on the Bank of England. In May 1806 with James Monroe then minister at London he was commissioned to treat with the British Government concerning the capture of neutral ships in time of war from 1807 to 1811 after Monroe's return to America he was resident minister in London. He was elected to the Maryland senate in Sept. 1811 and later was attorney general of the United States until 1814. In Aug. 1814 he was wounded at Bladensburg. He served in the National house of representatives Jan-April 1816 and from 1816-18 was minister plenipotentiary to Russia and special minister to Naples where he attempted to secure indemnity for the losses to American merchants by seizure and confiscation during the rule of Murat in 1809. He was a member of the committee which drew up the Missouri Compromise (qv). He was a member of the United States Senate from 1810 until his death at Washington on Feb. 5, 1822.

See William Pinkney *The Life of William Pinkney* (1853) (1810-83) Henry Wheaton *Some Account of the Life Writings and Speeches of William Pinkney* (1828)

**PINNACLE**, in architecture any vertical decorative motive serving as the upper termination of a building or other form hence metaphorically a summit or topmost limit. The word is distinguished from finial (qv) as signifying a larger motive sometimes of considerable complexity whereas a finial is a single ornament and from tower or turret by the fact that a pinnacle is always a strictly subsidiary motive. Thus a Gothic tower and spire may be decorated with pinnacles each one of which is capped by a finial. The chief architectural development of the pinnacle was in connection with buttresses (qv) of late Romanesque and Gothic buildings as the addition of a pinnacle to a buttress not only added to the stability by increasing the weight but also gave a decorative termination to the vertical line. Earlier pinnacles are simple square or rectangular structures capped with gable roofs or small spires as in St. Remi at Reims (middle 12th century) and in the west front of Rochester cathedral (1130). With the development of the flying buttress (qv) pinnacles were increased greatly in size and especially in France in richness and usually decorated with colonnettes on the outer corners and arches and crocketed gables above, sometimes with the addition of slender crocketed

spires. Those of Notre Dame at Paris (end of 12th and beginning of 13th centuries) are typical. The most beautiful of the developed Gothic buttress pinnacles are those of the choir of Reims cathedral (c. 140) in which the solid portion is preceded by an open shrine with a statue of an angel. In England pinnacles were especially developed during the Decorated Period (qv) and play an important part in the tower designs in which they serve to soften the transition between a square tower and a spire above. Characteristic examples are those of Beverley minster (c. 1350) and the tower of St. Mary's at Oxford (c. 1300).

The modern emphasis on vertical lines resulting from steel construction has led to a recrudescence of the use of pinnacles and especially in the tall buildings of America they are common decorations of the skyline and of the various set backs.

**PINOCLE** is a game of cards similar to the French game of bezique. It can be played by two, three or four persons.

**Short Pinocle** is played with two packs from which all cards below the 9s are left out. The cards remaining are in order of value 9 knave queen king 10 ace (high). Twelve cards are dealt to each player four at a time and the next card is turned as a trump. It is placed under the pack face up. If it is a 9 it is called the dix (pronounced deuce) and the dealer scores 10 points for turning it. If any other card is turned either player who has a 9 of trumps after he has taken a trick may take up the turned trump into his hand and put his 9 face up under the pack and score 10 points for his 9. The holder of the other dix may lay it on the table after he has taken a trick and add 10 to his score.

The scoring is done by melding a word which comes from a German verb *melden* to announce. After either player has taken a trick he can lay the cards to be melded on the table face up and add the value of that meld to the score but only one meld can be made after each trick taken. The values of the meld are as follows: the dix is 10 a marriage (any king and queen of same suit) 20 a royal marriage (a king and queen of trumps) 40 pinocle (the knave of diamonds and queen of spades) 40 4 aces of different suits 100 4 kings of different suits 80 4 queens of different suits 60 4 knaves of different suits 40 a royal straight (ace 10 king queen and knave of trumps) 150.

In melding at least one new card must be laid out for each new meld. For instance with spades for trumps holding 150 the king and queen should be laid out first and 40 trumps melded then after taking another trick the ace 10 and knave are laid down and 150 melded. Then if the player has the knave of diamonds after taking another trick it may be laid by the queen of spades and pinocle melded. This order of melding however can only be followed when there are enough cards left in stock to be sure the player will have time as no meld can be made after the last card is drawn from the stock. Otherwise 150 should be melded at once.

The cards left after the trump is turned are called stock cards and after each trick is taken in and laid away face down each player draws a card the winner drawing first. After they draw no player can meld until he has taken another trick. Each player keeps in mind a count of the cards he has taken in play. They count as follows: aces 11 tens 10 kings 4 queens 3 and knaves 2 points and he adds the total of those made to his melding score. The player who takes the last trick also adds 10. The total of the points in the two hands including the last trick is 250.

A player may follow suit trump or discard but after the last stock card has been drawn each must follow suit or trump. If void both of the suit and trump he may discard. One who violates this law loses the cards in the tricks he has won in that hand. The game is 1000 points and when a player who has the lead believes that the value of cards in the tricks he has taken added to the points he has already scored equals 1000 he may call out and stop the play. If he is short of the points he loses the game.

**Auction Pinocle** has generally taken the place of short pinocle. Only in number of cards used the values of the melds and the values of the cards and dices are the games the same. Only three can play auction pinocle. If a fourth takes part each dealer in turn takes no cards and sits out during the play but wins or loses the same as those who play against the successful bidder.

PINNACLE LEFT NOTRE DAME PARIS RIGHT REIMS CATHEDRAL

Fifteen cards are dealt to each player usually three at a time and at some time during the deal three cards are dealt to the table face down and remain there. The cards are often called the widow or dummy. Each player in turn beginning with the eldest hand may pass or may bid for the privilege of declaring the trump and playing the hand. If all pass the hand is thrown up and he is a new deal. If bids are made the first bid usually must be at least 100 or 50 (in some clubs at least 300) but may be whatever more the bidder thinks he can make. Each time owing bid must be at least 10 more and the bidding continues until two players have passed. A player who has passed cannot bid again on that hand. When two pass the bidding stops and the contractor goes to the last bidder who becomes the contractor. The contractor now turns the three cards in the widow face up on the table and adds them to his hand. He declares a trump and lays his melds on the table face up. In addition to the melds given above the contractor may meld a round trip 40 if he holds a king and a queen in each suit but if he makes this meld a royal straight counts only 110. If these values added make his bid he has won his contract and the other players pay but if after counting his melds and dives he is short of the points bid and his opponents refuse to concede the contract he may play the hand and try to make up the shortage from the count of the cards in the tricks he takes. If he feels he cannot make his bid he does not play but pays.

If the contractor decides to play he takes all the cards up from the table lays three not melded face down from his own hand which count as a trick for him. If he fails to lay these cards out he loses. If he lays a trump he must announce it. He now leads and the other two are partners against him. In the play of the hand every player must follow suit or trump. If void both of the suit led and trumps a player may discard any card on the trick. If trumps are led each player that follows must play a higher card and win the trick if he can. If void of trumps he may discard. The last trick counts ten for the one who wins it. If the number of points made by the value of the cards in the tricks the contractor wins added to the points in his meld make the number that he has bid, he collects for the number of points bid from the players no matter how many points he has made. If the bid is 300 and he makes 500 points he can only collect for 300. If the contractor plays the hand and fails to make his contract he must pay double.

Each deal is a complete game and is usually paid for at once by the losers. For convenience instead of keeping a score each player usually takes 25 poker chips. At the end of the hand each player pays 2 chips for any loss under 300, 3 chips for a loss between 300 and 340, 5 chips for a loss from 350 to 390, 10 chips for a loss from 400 to 440, 15 chips for a loss from 450 to 490, 20 chips for a loss of 500. These figures are purely arbitrary. Players give any value they wish to each chip. At the end of the sitting each player owes for the 25 chips he had at the beginning and collects for all the chips he has won or pays for all the chips he has lost. (C L P)

**PINSK**, a town of Poland in the province of Polesie at the confluence of the Strumen and Pina rivers 196 m SW by rail of Minsk. The river Pina connects it with the fertile regions in the basin of the Dnieper and by means of the Dnieper and Bug canal with Poland and Prussia while the Oginski canal connects it with the basin of the Niemen. Pottery leather oil soap and beer are the chief products of the local industries. The draining of the marshes around Pinsk was begun by the Russian government in 1872 and by 1897 8 000 000 acres had been drained at an average cost of 3s per acre. Pinsk (Pinesk) is first mentioned in 1097 as a town belonging to Sviatopolk prince of Kiev. In 1132 it formed part of the Minsk principality. After the Mongol invasion of 1239-42 it became the chief town of a separate principality and continued to be so until the end of the 13th century. In 1520 it was annexed to Lithuania and in 1569 after the union of Lithuania with Poland it was chief town of the province of Brest. Pinsk was annexed to Russia in 1795 and restored to Poland in 1918.

**PINT**, a liquid measure of capacity equivalent to  $\frac{1}{8}$  of a gallon (derived probably through Spanish from Lat *pincta picta* a

painted or marked vessel). The imperial British pint = 57 of a litre 34.66 cu in. The United States standard pint = 47 of a litre 8 cu in.

**PINTO, FERNAO MENDES** (1509-1583) Portuguese adventurer & sailor born at Montemor o Velho of poor parents and entered the service of a noble lady in Lisbon. He embarked for India in a fleet commanded by the son of Vasco da Gama and for 1 year travelled fought and traded in China Tartary Pegu and the neighbouring countries sailing in every sea and introducing the musket into Japan. Though he was 13 times a captive and 17 times sold into slavery his gay and dauntless spirit broadened him through every misfortune. He was soldier and sailor merchant and doctor missionary and ambassador moreover as the friend and travelling companion of St Francis Xavier he lent the apostle of the Indies the money with which to build the first Jesuit establishment in Japan.

In Jan 1544 Pinto was in Goa waiting for a ship to take him to Portugal when he decided to devote a large part of his capital to the evangelization of Japan. The viceroy appointed him ambassador to the king of Bungo in order to give the mission an official standing and on April 18th he set sail with the provincial Father Belchior Nunes. The missionaries did not reach Japan until July 1566. On Nov 14 1556 Father Belchior and Mendes Pinto began their return voyage and reached Goa on Feb 17 1557. During his stay of a twelve month there Pinto left the company being dispensed from his vows for want of vocation at his own request though a modern authority states that he was expelled because he was a *marrano* i.e. had Jewish blood. He finally returned to Portugal on Sept 1558 and settled at Pragal near Almada where he married and wrote his famous book the *Peregrination* the manuscript in fulfilment of his wishes was presented by his daughter to the Casa Pia for penitent women in Lisbon and it was published by the administrators in 1614. Philip II of Spain gave him (1583) a pension for his services in the Indies. But the reward came too late for he died on July 8.

Pinto was on the whole a careful observer and truthful narrator but he invented on occasion and often repeats stories at second hand. Some witty Portuguese parodied his name into *Fernao mentes? Pinto!* (Ferdinand do you lie? I do!) and the English dramatist Congreve only expressed the general opinion of the unlearned when he wrote in *Love for Love* Mendes Pinto was but a type of thee thou liar of the first magnitude. In the narrative portions of his work Pinto's style is simple clear and natural. He did for the prose of Portugal what Camoens did for its poetry.

The *Peregrination* has gone through many editions subsequent to that of 1614 and in 1865 Castilho published excerpts in his *Livreria classica portugueza* with an interesting notice of Mendes Pinto's life and writings. Versions exist in German (3 editions) French (3 editions) Spanish (4 editions) and in English by Henry Cogan London (1663 1692 and—abridged and illustrated with introduction by Arminius Vambery—1891). Cogan omits the chapters relating to Mendes Pinto's intercourse with and the last days of St Francis Xavier presumably as a concession to anti Catholic prejudice.

See Christovao Ayres *Fernao Mendes Pinto* (Lisbon 1904) *Fernao Mendes Pinto e o Japao* (Lisbon 1906) also *Subsidios para a biographia de Fernao Mendes Pinto* by Jordao de Freitas (Coimbra 1905).

**PINTO** The brown black and blue spots of discoloration of the whole body endemic in Mexico Panama Colombia and Venezuela and known under the name were first held by Gastambide (*Presse med Belge* 1881 Nos 33-41) as due to a vegetable parasite whose spores and mycelial filaments may be detected among the deeper rows of cells of the rete mucosum. The disease appears to be one of poverty but it is contagious and is some times seen in the well to do. In villages of Tabasco (Mexico) it is said that 9% of the people thus suffer.

**PINTURICCHIO** (1454-1513) Italian painter of the Umbrian School whose full name was BERNARDINO DI BETTO (BENEDETTO) DI BIAGIO the son of a citizen of Perugia, Benedetto or Betto di Biagio. He was probably a pupil of Fiorenzo di Lorenzo and the two masters appear to have co-operated in the execution of the Adoration of the Magi from S Maria Nuova now in the Pinacoteca of Perugia. After assisting Perugino in

the execution of his frescoes in the Sistine Chapel Pinturicchio was employed by Niccolò Buffalini advocate to the papal consistory to decorate a little Gothic chapel in Ara Coeli on the Capitol with frescoes illustrating the life of San Bernardino of Siena. These frescoes were probably executed about 1484. They show the master at his best. The colouring is exceedingly harmonious, the landscape backgrounds full of atmosphere. Pinturicchio was employed by the Della Rovere family to decorate a series of chapels in the church of S. Maria del Popolo. The Adoration of the Shepherds in the chapel built by Cardinal Domenico della Rovere was probably done about 1500. In the lunettes under the vault Pinturicchio's assistants painted small scenes from the life of St. Jerome.

The last paintings completed by Pinturicchio in this church were the frescoes on the vault over the retro choir, a very rich and well designed piece of decorative work with main lines arranged to suit their surroundings in a very skilful way. No finer decoration of a quadripartite vault exists.

In 1499 Pinturicchio was summoned to Orvieto where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome and was employed by Pope Alexander VI (Borgia) to decorate a suite of six rooms in the Vatican which Alexander had just built. Of these rooms called after their founder the *Appartamenti Borgia* five still retain his frescoes. The upper parts of the walls and vaults are not only covered with painting but further enriched with delicate stucco work in relief. Pinturicchio employed many assistants. The second room however with scenes from the lives of saints was painted by the master himself and contains one of his famous works, The Dispute of St. Catherine.

On the vault of the sacristy of S. Cecilia in Trastevere Pinturicchio painted the Almihty surrounded by the Evangelists. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now like the rest of his work at Orvieto almost destroyed.

Among his panel pictures the following are the most important. An altarpiece for S. Maria de Fossi at Perugia painted in 1496–1498 now moved to the picture gallery is a Madonna enthroned among saints graceful and sweet in expression. Another fine altarpiece similar in delicacy of detail and probably painted about the same time is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin with the apostles and other saints below. Several well executed portraits occur among the kneeling saints. Other panel paintings by Pinturicchio exist in the cathedral of Spello in the Siena gallery at Perugia and in the collection of the Earl of Crawford at Haigh Hall.

In 1501 Pinturicchio painted several fine frescoes in S. Maria Maggiore at Spello—all very decorative and full of elaborate architectural accessories. One of them the Annunciation is signed Bernardinus Pinturichius Pervinus. The most striking of all Pinturicchio's frescoes both for brilliance of colour and their wonderful state of preservation are those in the cathedral library at Siena, a large room built in 1492 by Cardinal Francesco Piccolomini afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault and on the walls ten scenes from the life of Aeneas Sylvius Piccolomini, Pius II, the uncle of Cardinal Francesco.

The contract specially provided that the cartoons, their transfer on to the walls and all the heads were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. The series were finished in 1507. Outside the library over the door we have the coronation of Pius III in which he has introduced his own portrait and standing by him is a youth who bears some resemblance to Raphael. In 1513 the year of his death he painted a highly finished panel with Christ bearing His Cross now in the Palazzo Borromeo in Milan. He died at Siena on Dec. 11, 1513, and is ranked as one of the greater Umbrian painters. His worth has been undervalued, partly owing to the dislike which tinges Vasari's biography of him. Even Crowe and Cavalcaselle hardly did him

justice. G. Morelli has however disproved the myth that Raphael then a youth of 10 supplied cartoons or drawings for the aged master in his work in the Libreria del Duomo, Siena. These drawings (Venice) are not by Raphael but by Pinturicchio.

See G. Morelli *Italian Masters in German Galleries* (1883), Vermiglioli *Memoire di Pinturicchio* (Perugia 1837) and the valuable notes and appendix of Milanesi's edition of Vasari iii 49–531 (Florence 1878). E. Steinmann *Pinturicchio* (Leipzig 1898). E. M. Phillips *Pinturicchio* (1901). W. Bombe *Geschichte der Peruginer Malerei* (1901).

**PINWELL, GEORGE JOHN** (184–1875) British water colour painter was born at Wycombe and educated at Heatherley's Academy. Like Frederick Walker and A. B. Houghton he belonged to a group whose style was derived from drawing upon wood for book illustration. As he died young his works are few but their promise was great. His earliest drawings appeared in *Lilliput Levee*. He did a little work for *Fun* and executed several designs for the silversmiths Elkingtons. In 1863 his first drawing appeared in *Once a Week* and from that time his work was in constant demand in current periodicals. His most important productions made for the Dalziel brothers were illustrations of Goldsmith of Jean Ingelow's poems Robert Buchanan's *Balads of the Affections* and the *Arabian Nights*. Of Pinwell's pictures in colour which are distinguished by a remarkable jewel like quality and marked by his strong love of pure bright colour and opalescent effect the chief are the two scenes from the *Pied Piper of Hamelin*, *Gilbert à Becket's Troth Out of Tune* or *The Old Cross*, *A Seat in St. James's Park* and *The Elixir of Life*.

In 1874 Pinwell fell seriously ill and went to Africa for the winter. He painted several remarkable pictures at Tangier but he returned to die on Sept. 8, 1875.

See G. C. Williamson *Life of George J. Pinwell* (1900).

(G. C. W. X.)

**PINZON**, a family of Spanish navigators of Palos in Andalusia, three members of which—Martin Alonzo, Francisco and Vicente Yanez brothers—were associated with Columbus in the discovery of America.

MARTIN ALONZO PINZON, born about the middle of the 15th century in the expedition of 1492 commanded the Pinta on which his brother Francisco was pilot. On Oct. 6 he suggested to Columbus (when already in the longitude of the Bermudas) to change the course of the expedition from due west to south west. On Oct. 7 this suggestion was adopted bringing the fleet to the landfall at Guanahani (San Salvador, Watling Island) in the Bahamas (Oct. 12, 1492). On Nov. 21 near the east end of the north coast of Cuba he left Columbus making eastward in search of the supposed gold land. On Jan. 6, 1493 he rejoined the admiral but on the return journey again left him and landed at Bayona in Galicia. He died soon afterwards.

VICENTE YANEZ PINZON commanded the Nina in 1492–1493 and remained loyal to Columbus throughout. In after years he made important discoveries on his own account. In December 1499 he sailed with four caravels across the Atlantic to the south west and on Feb. 7, 1500 he landed at Cape S. Agostinho near its most easterly projection (called by him Cape Santa Maria de la Consolacion). Proceeding southwards a short distance he then turned north followed the coast to the north west discovered the Amazon estuary and went as far as what is now Costa Rica. After touching at Haiti and losing two of his vessels among the Bahamas Vicente returned to Palos in September 1500. Although he was created governor of the newly discovered lands by Ferdinand and Isabella he did not take possession. In 1507 he sailed with Juan Diaz de Solis along the east coast of Central America. In 1509 again with De Solis he coasted the Atlantic side of South America as far as the La Plata estuary hoping to find an opening westwards leading to the Spice Islands. According to Herrera he reached 40° S. not recognizing the La Plata and turning back about the mouth of the Rio Negro, but this is probably an exaggeration. After 1523 all traces of Vicente are lost.

**PIOMBINO**, a seaport of Tuscany Italy in the province of Livorno 8 m by rail W S W of Campiglia Marittima (which is m S S E of Pisa) 6 m above sea level at the southern extremity of the peninsula of the Monte Masoello Pop (1931) 9 (town) 6 (commune) It is the port of embarkation for Elba the nearest point of which is about 6 m to the south west and originally belonged to Pisa It gives the title of prince to the Buoncompagni Ludovisi family who however no longer own it Large iron smelting and tin plate works are situated here In 1906 599 ships of 945 18 tons entered and cleared the port while at Portoterraio in Elba 6184 ships of 11443 tons entered and cleared

**PIOTRKOW**, a town of Poland in the province of Lodz and formerly the seat of the high court of Poland on the railway from Warsaw to Vienna 90 m south west of the former and 5 m west of the river Pilica Pop (1931) 51 81 It is a well kept town with numerous gardens and has flour mills saw mills tanneries agricultural machinery works and breweries One of the oldest towns in Poland Piotrkow was in the 15th and 16th centuries the place of meeting of the diets and here the kings were elected

**PIOZZI, HESTER LYNCH** (1741-181) English writer well known as the friend (Mrs Thrale) of Samuel Johnson was born on Jan 16 1741 her father being John Salubury of Bobbel Carnarvonshire In 1765 she married Henry Thrale a rich Southwark brewer whose house was at Streatham on the south east corner of Tooting Bec Common There was very little sympathy between the lively girl and Thrale who was 13 years her senior but gradually she drew round her a distinguished circle of friends

She was introduced to Samuel Johnson in 1765 by Arthur Murphy who was an old friend of her husband's In 1766 Johnson paid a long visit to Streatham and from that time was more or less domesticated with the Thrales (See JOHNSON SAMUEL) Fanny Burney was another of her friends She was very sensitive and sometimes thought that Mrs Thrale gave herself airs of patronage Meanwhile in 1772 Thrale was threatened with bankruptcy The situation was saved by his wife's efforts and in the next year Thrale travelled leaving her in charge of his affairs He was twice returned for the borough of Southwark chiefly through her efforts In 1781 Thrale died and Dr Johnson helped the widow with her business arrangements advising her to keep on the brewery until she cured his honest heart of its incipient passion for trade by letting him into some and only some of its mysteries The brewery was finally sold for £135 000

Mrs Thrale had met Gabriele Piozzi an Italian musician in 1780 In 1784 they were married Johnson told Miss Burney that he drove the memory of Mrs Thrale from his mind by burning every letter of hers on which he could lay his hand The Piozzis presently left England to travel in Italy At Florence they fell in with Robert Merry and the other Della Cruscan writers ridiculed by William Gifford in his *Maeiad* and *Baviad* and she contributed some verses to their *Florence Miscellany* in 1785 In 1786 she published *Anecdotes of the late Samuel Johnson during the last twenty years of his life* which was severely criticized by Boswell She was ridiculed by Peter Pindar in *Bozzy and Piozzi or the British Biographers A Town Eclogue* (1786) But though Miss Burney and some others held aloof the Piozzis found plenty of friends when they returned to London in 1787 Piozzi died at Brynbella a villa he had built on his wife's Flintshire estate in 1809 and Mrs Piozzi gave up her Welsh property to her adopted son and spent most of the rest of her life at Bath and Clifton She retained her vivacity to the last celebrating her 80th birthday by a ball to six or seven hundred people at Bath She died at Clifton on May 2 1821

From 1776 to 1809 she kept a note book which she called *Thraliana* Her well known poem of the *Three Warnings* is to be found in many popular collections *Letters to and from the late Samuel Johnson* appeared in 1788 *Observations and Reflections made in the course of a Journey through France Italy and Germany* in 1789 and in 1801 she published *Retrospection or a review of the most*

**PIPE**, a hollow stem of clay wood or other material with a bowl at one end used for smoking tobacco opium or other narcotic or any medicinal substance See PIPE SMOKING and TOBACCO PIPE

**PIPE and TABOR**, a popular mediaeval combination of a mail pipe or flageolet and a small drum The tabor being fastened

OF 7  
THE PIPE AND TABOR STILL IN USE  
IN CERTAIN PARTS OF FRANCE

to the performer's left elbow the hands remained free the right beating the little drum with a stick to mark the rhythm while the left held and fingered the pipe with thumb and first two fingers The pipe and tabor are said to be of Provençal origin

**PIPE CLAY** A natural clay one of the names given to impure kaolin or china clay It occurs in beds where kaolin has been washed away from its original site and deposited in a hollow It is used to make primitive tobacco pipes and for whitening military belts etc

**PIPE FISH**, the name given to fishes which with the sea horses form the family *Syngnathidae* of the order *Solenichthyes*

The pipe fishes are long and slender with the body encased in bony rings and a small toothless mouth at the end of a long tube like snout the gill filaments are reduced in number and appear as rounded lobes or tufts About 100 species are known from warm seas and a few from rivers Pipe fishes frequent sea weeds and swim slowly by rapid undulations of the small dorsal fin

**PIPE-LINE** see PETROLEUM

**PIPER, CARL, COUNT** (1647-1716) Swedish statesman was born at Stockholm on July 29 1647 In 1689 he was made one of the secretaries of state and Charles XI recommended him on his deathbed to his son and successor Charles XII Piper became the most confidential of the new sovereign's ministers In 1697 he was made a senator and set over domestic affairs while still retaining his state secretaryship In 1698 he was created a count in 1702 appointed chancellor of Uppsala University and during the first half of the Great Northern War as the chief of Charles's perambulating chancellery he was practically prime minister But he belonged to the school of Bengt Oxenstierna (qv) and was therefore an avowed advocate of a pacific policy He protested in vain against nearly all the military ventures of Charles XII eg the War of Deposition against Augustus of Saxony and Poland the invasion of Saxony the raid into the Ukraine Again and again he insisted that the pacific overtures of Peter the Great should at least be fairly considered but his master was always immovable Piper was taken prisoner at Poltava (1709) and died at Schlüsselburg on May 29 1716

(R N B)

**PIPERACEAE** in botany the pepper family comprising seven genera with 1150 species tropical herbs and shrubs The leaves have a pungent flavour and the flowers lack both calyx and corolla *Piper* includes the pepper (qv)

**PIPERAZINE**, a colourless crystalline solid melting at 104 C and boiling at 145 C soluble in water and used medicinally as a uric acid eliminant Piperazine  $C_4H_{10}N_2$  was first obtained by A v Hofmann by the action of ammonia on ethylene dichloride or dibromide It is manufactured from the latter dihalide and aniline the intermediate product diphenylpiperazine being converted successively into its dinitroso compound and piperazine

**PIPERINE**, an alkaloid (*see* ALKALOIDS) found in the fruits of certain peppers It forms white prism melts at 15–19 C is almost insoluble in water but readily so in alcohol or ether and is a very weak base salts being only formed with mineral acids and these are dissociated by water Alcoholic potash decomposes piperine  $C_8H_{13}ON$  into piperidine  $C_4H_9N$  and piperic acid  $C_4H_5O$  indicating that the alkaloid is a piperide of piperonylic acid It was synthesized (Rugheimer 188) by the action of piperonyl chloride on piperidine

**PIPERITONE** is the sole ketonic constituent of eucalyptus oils from which it may be either fractionally distilled or extracted with sodium bisulphate It occurs in the peppermint group of eucalyptus leaf oils in association with *l*- $\alpha$ -phellandrene and has been found altogether in 5 species these grow mainly in south eastern Australia and Tasmania and are characterized by a butterfly wing leaf venation A maximum content of about 45% of piperitone is reached in the oil of the Broad leaved Peppermint (*E. dives*) Piperitone  $C_{10}H_{16}O$   $\Delta^1$ -menthen-3-one is a colourless liquid (b.p. 23.2) with an odour of peppermint The eucalyptus ketone is laevo rotatory with  $[\alpha]_D^{25} -53.9$  but *d* piperitone having  $[\alpha]_D^{25} -62.5$  has been isolated from the essential oil of a Himalayan grass *Andropogon Iwarancusa* The optically active ketone racemizes easily owing to enolization When hydrogenated according to Paal's method *l* piperitone yields mainly *d*-iso menthone and by reduction in other ways it has been used commercially as a source of *dl* menthol It may be oxidized to thymol

**PIPERNO** (anc. *Privernum*) a town of the province of Rome Italy 54 m SE of Rome by rail Pop (1951) 8,488 The mediaeval town was founded in the 10th century on a hill 490 ft above sea level by refugees from the Roman town of Privernum lower down (118 ft above sea level) on the high road 1½ m to the north at the mouth of a low pass leading through the Volscian mountains to the valley of the Sacco Here are scanty remains of the Roman period though the ruins are largely mediaeval The ancient Volscian town probably stood on the site occupied by the mediaeval and modern town Privernum was finally captured in 39 BC and in 318 the tribus Oufentina was founded (*see* LATIUM) The mediaeval town has a picturesque piazza with a Gothic cathedral (1283) and a Gothic town hall and Gothic churches Polygonal terrace walls of the Roman or pre Roman period exist at various places in the vicinity

**PIPE ROLLS** or the Great Rolls of the Exchequer are a long series of financial records of the English crown The first extant Pipe Roll is that for the 31st year of the reign of Henry I The continuous series begins with the second year of Henry II's reign and the annual succession of rolls is almost unbroken till 1834 when the last relics of the ancient financial system of the English mediaeval kings were swept away The most plausible explanation of the name Pipe Rolls is that when rolled up and stacked on their presses the rolls looked like pipes Up to the beginning of the 13th century the Pipe Rolls are the only consecutive series of official records which have survived it was not until the reign of John that the Chancery records were systematically preserved Therefore the value of the Pipe Rolls for the last half of the 12th century can hardly be overestimated By them the narratives of the chroniclers can be checked and from them most of our knowledge of the actual working of the legal system in Henry II's reign comes They are a mine of information about the personnel of the government and the gradual development of the new administrative offices They are the best authority for the descents of the great families of feudal England For the historian of English towns they provide a vast mass of material Calculations as to the amount of the royal revenue

have been made from them but such calculations can only be approximate since much money was paid directly into the king's privy purse and recorded in no roll that survives

Consisting of a varying number of skins of parchment about 14 inches wide and a yard long sewn together at the top the rolls are not easy to consult Their matter too is not easy reading nor their method of book keeping easy to understand The accounts are entered county by county the sheriff being responsible for the account of his shire Other accounts known as foreign accounts appear sometime on the rolls accounts of royal manors by their custodians accounts of escheats or of towns The clerks enter debts long after all hope that they may be paid has passed away In 1885 the Pipe Roll Society was formed to publish the rolls up to 100 It hopes to carry the work up to the end of John's reign In later centuries the Pipe Rolls lose much of their importance but interesting matter can be found in the foreign accounts which continue to appear on the rolls When the escheat rolls begin one great source of foreign accounts is lost to the Pipe Rolls In this way by a process of splitting off and the setting up of new accounting offices the ancient sheriff's account recorded in the Pipe Rolls becomes insignificant and stereotyped The continuation of the series to 1834 is a remarkable illustration of English administrative conservatism (D M S)

**PIPERONAL**, an aromatic aldehyde with an agreeable smell resembling that of heliotrope It forms long colourless crystals which melt at 37 C and boil at 265 C and is much used in perfumery It is only slightly soluble in cold water but readily soluble in alcohol and in ether It is also called heliotropine and is protocatechuic aldehyde methylene ether  $CHO \cdot CH \cdot CHO$  It is prepared by oxidizing piperic acid with potassium permanganate (R Fittig 1869) by condensing methylene iodide with protocatechuic aldehyde (R Wegscheider 1893) or by oxidizing isosafrole with chromic acid When heated with dilute hydrochloric acid to 200 C it yields protocatechuic aldehyde  $CHO$  and carbon It readily combines with sodium bisulphite and with various bases (ammonia aniline methylamine etc)

**PIPE SMOKING** The original source of the idea of smoking must be sought in the sense of smell This was much keener in primitive man than in man of the more advanced stages With the pleasure derived from aroma there was probably a sense of mystery at the sight of the smoke rising up into the air Thus there was an element of religious ceremony in the burning of pleasant smelling substances among primitive folk in whatever part of the world we may be able to study their ways

The ritual element is enhanced by another circumstance Herodotus in the fifth century BC describes a practice of the Scythians a Mongol people settled in south eastern Europe between the Carpathian mountains and the River Don Throwing the leaves of a certain plant (which was probably hemp) upon a fire they sit round and inhaling the smoke they grow drunk with the fumes as the Greeks do with wine until they jump up and begin to dance and sing Herodotus seemed to regard this simply as an orgy but inhalation was certainly used to produce a super normal condition of mind in many parts of the world When Columbus discovered America he found the habit established of inhaling tobacco to induce a state of trance during which visions were seen which were accepted as divine revelations The intoxicating vapour at Delphi which inspired the Pythian priestess may have been artificially produced since no natural source has been found

The invention of an implement to concentrate the smoke was an advance Such an implement is the Y shaped tube described by G Fernandez de Oviedo in his *History of the Indies* (1535) The two horns of the Y were inserted in the nostrils and smoke from tobacco burning in a censer was drawn up through the tube This was the ceremonial method of smoking prevalent in the Antilles when Columbus and his followers reached them side by side with a common use of the tobacco leaf rolled up and smoked like a cigar Bernal Diaz who accompanied Cortez to Mexico describes the inhalation of tobacco through a tube But we have much earlier evidence from Mexico At the ruined city of Palenque in the southern province of Chiapas there are the

remains of a Temple of the Cross which seems to belong to the beginning of the second century AD. Here on one of two stone slabs on either side of a doorway is represented a figure of a priest clad in a jaguar skin cloak and a head dress representing a mythical bird who is blowing out a smoke offering through a straight tube. This Palenque sculpture is the work of the Maya, the mysterious race which preceded the Toltecs and the Aztecs in Mexico. Other Maya sculptures portray the straight smoking tube both as an emblem in one of the hands of Chac, the god alike of rain and thunder and of fertility, and as an apparently ordinary implement for smoking. Lionel Wafer at the end of the 18th century speaks of a roll of tobacco fitted on a long and as thick as a man's wrist being lighted by a boy and the smoke being puffed into the faces of a company who made funnels of their hands and inhaled it.

Whatever the original use of the straight tube (which is found in a variety of materials—bone, wood, cane, stone of kinds not too hard to work, and pottery), the use of it as a pipe for tobacco comes before America was discovered by the early European adventurers is well established. The first modification of the type is that found in the burial mounds of the Muskogean Indian in the south-eastern portion of what is now the United States. The tube is bent up at one end with a widening of the bowl formed by this end. Pipes on the lines were obviously the model for the clay pipe as known to Europe, which is only natural since the first Europeans to introduce the use of the tobacco pipe into their own countries learned the habit of smoking not from the West Indies but from the Indians of the eastern mainland.

The next modification of the tube which is found in Ohio and Virginia in the burial mounds of another Indian tribe, the Algonquians, converts it from a one-piece to a two-piece pipe. Whatever the material used, usually some kind of stone, the stem was liable to be broken necessitating a makeshift stem if the bowl was to continue in use. From this the transition is easy to a bowl alone into which a wooden stem could be inserted.

While the tobacco pipe was thus evolving in North America, apparently a two-piece pipe arose independently in South America. In the upper part of the southern continent true pipes were not used though the Y-shaped tube of which we have already heard was employed for inhaling snuff. Otherwise cigar smoking was the ordinary form of indulgence in tobacco. But in South Brazil in 1650 the traveller Jan Nieuwhoff found a great Indian tribe smoking pipes with bowls made of nut shells and with stems of reed or hollowed wood. This kind of pipe with a small bowl was the prototype of the pipes of Turkey, Persia and the Far East, since the Portuguese took it with them from Brazil along their trade route in the Old World. Much larger pipes were also used by the same Brazilian tribe with bowls of stone, clay or wood and are found to day among their descendants now living on the Upper Amazon.

The two-piece pipe is also found in the steppes of Central and Western Asia and the Kalahari region of South Africa. Both these are wordless countries, scantily inhabited by people mostly nomadic. Here earth smoking is found. The most primitive method is to dig a small pit in the ground to serve as a bowl, to insert a stick through the earth to the bottom of this pit and then to withdraw the stick leaving a hollow tube. The smoker has to lie flat on the ground and apply his mouth to the end of the tube. An improvement on this uncomfortable method is the fashioning of a rough bowl of clay above the surface of the ground with a tube formed as before with the aid of a stick. Such an earth pipe when dry can be detached and carried about. The insertion of a separate mouthpiece into the end of the hollow tube would convert it into a two-piece pipe. In quite a different part of the world among some of the North American Indians a hollow reed stuck into a bowl made of wet clay is said to serve as an emergency pipe.

The credit of the first invention of the pipe cannot be assigned to any one people nor is it certain that smoke proceeded always from tobacco leaf. There is hemp which in many parts of the world at least long preceded tobacco. There are many herbs, such as henbane, which were commonly used in Europe for how many

centuries we do not know. Opium smoking on the other hand is a late development. Early evidence concerning the tobacco pipe comes from America only for the reason that the tobacco plant is a native of America. The theory that both the plant and the habit of smoking derived originally from Africa and reached the western coast of America by way of the Indian and Pacific Ocean rests on an insufficient basis. Smoking, no doubt, is a custom of great antiquity in Africa, but it is the smoking of hemp, exemplified notably among the Bushmen of the Kalahari Desert. The evolution in Africa of the pipe for hemp smoking has so far as we can tell been from the earth pit through the simple tube to the *Dakka* (hemp) pipe which is the ancestor of the water pipes of various kinds used for tobacco in the East. Among the Bushmen an animal's horn, generally an antelope's, is used as the water vessel. Among other African tribes ox horns, gourds, banboos and wooden stems are to be seen. It was thus the African hemp smokers who gave to the smokers of tobacco this idea of using a pipe in which fumes should be filtered and cooled by passing through water.

See A. Dunhill *The Pipe* (1924), the *British Museum Handbook to the Ethnographical Collection* (2nd ed. 1925), the *British Museum Guide to the Maya Collection* (1933). (A. D.)

**PIPIL**, a dialect of the Nahuatl or Aztec language. In southern Mexico, Guatemala and western Salvador there are four groups of Indians who speak a Nahuatl dialect related to but more primitive than Aztec. These four groups are (1) *Pipil of Soconusco*, (2) *Pipil of the upper Motagua valley*, (3) *Pipil of Escuintla* and (4) *Pipil of Salvador*. At the time of the Spanish conquest several explanations of the presence of these Mexican Indians in Central America were given by the natives. It was said that the Aztec emperor Ahuitzotl (1486-1502) sent colonists to spy out the land and prepare for a never accomplished conquest. This tale fails to account for the large and well built cities occupied by the Pipil. More generally it is thought that they were Toltec (*qv*) who either migrated from Mexico with one of the early priest-kings named Quetzalcoatl or more probably fled after the downfall of the Toltec empire in the 11th century. The Spanish historian Juan de Torquemada in support of the last hypothesis has preserved a significant migration legend. Numerous ruined cities are attributed to the Pipil by archaeologists. Of these the most important are Santa Lucia Cazumalhuapal and Baul in Guatemala and Chalchuapa, Cihuatlan and Tehuacan in Salvador. These sites yield characteristic stone carvings and pottery types. The present culture of the Pipil varies from village to village. In general it reflects that of their neighbours such as the Quiche (*qv*).

**PIPPIT**, a sub-family of birds having a great resemblance in habits and appearance to the larks (*qv*). They differ however in several important characters. They are associated with the wagtails (*qv*) in the Passerine family *Motacillidae*. Pippits of which over 50 species have been described occur in almost all parts of the world but in North America are represented by only two species—*Neocorys spraguei*, the prairie lark of the north-western plains and *Anthus ludovicianus*, the American titlark, which last is nearly allied to the water pippit of Europe *A. spioletta*. To English readers the best known species is the titlark or meadow pippit *A. pratensis*, a bird abundant on pastures, moors and uncultivated districts generally, but in some localities the tree pippit *A. arboreus* takes its place and where it does so it attracts attention by its loud song which is delivered (as in all the pippits) on the wing. Another species, the rock pippit *A. obscurus*, scarcely ever leaves the sea coast and is found almost all round the British Islands. The South African genus *Macronyx* remarkable for the extreme length of its hind claw differs and has brighter coloration.

**PIPPIN** or **PEPIN**, the name of three members of the Carolingian family.

PIPPIN I (d 639) incorrectly called Pippin of Landen was mayor of the palace to the youthful Dagobert I whom Clotaire I had placed over the kingdom of Austrasia. He was disgraced when Dagobert became sole king in 639 and had to seek refuge in Aquitaine. Returning at Dagobert's death (638) he governed Austrasia in Sigebert's name but died the following year.

PIPPIN II (d 641) incorrectly called Pippin of Herstal was son of Adaliselus (son of Arnulf bishop of Metz) by a daughter of Pippin I. Called in later documents Berga. Towards 648 he placed himself at the head of the great nobles in Austrasia to combat Ebbo, the mayor of the palace and Neustria. After some reverses he gained a great victory after Ebbo's death at the battle of Tertry (68) not far from St. Quentin which marks the fall of the Merovingians. He appointed one of his grandsons Theodebald mayor of the palace of Neustria reserving for two others (Arnulf and Hugo) the mayoralty of Austrasia. He made war on the Frisians and defeated their duke Radbod and part of this people became converts to Christianity. He also defeated the Alamanni and subdued their country. The only part of Gaul not under his suzerainty was Aquitaine. The plans he had formed for reforming the church and convoking councils were interrupted by his death on Dec 16, 64.

PIPPIN III (d 768) the Short was the younger son of Charles Martel. Before his death in 741 Charles Martel had divided the Frankish kingdom between his two sons Carloman and Pippin, giving Carloman the eastern part and Pippin the western. Since 737 there had been no king in the Frankish realm; in the diplomas the two brothers bear the title of *maiores palatii* while the chroniclers call them simply *principes*. In 743 however the mayors decided to appoint a king in the person of Childeric III who was apparently connected with the Merovingian family. But Childeric was a mere figure head and had no power. The two brothers presided over the tribunals convoked the councils at which the Frankish Church was reformed, assembled the host and made war jointly defeating and subduing Duke Hunald of Aquitaine. In 741 Carloman unexpectedly abdicated, became a monk and retired to a monastery near Rome, subsequently founding on Mt Soracte the monastery of St. Silvester. From the time of the abdication Pippin was sole master and in 751 after consulting Pope Zacharias he held an assembly of the Franks at Soissons took the title of king and removed the feeble Childeric to a monastery. He then got himself crowned by St. Boniface a ceremony which was new to France and which gave the sovereign immense prestige; henceforth the king of the Franks called himself *Gratia Dei rex Francorum*. Pippin's reign is marked by many important events. He received in France a personal visit from Pope Stephen II who conferred on him the title of Patrician of the Romans and recrowned him. In return for these honours Pippin at the appeal of the pope made two expeditions into Italy in 754 and 756 and he became the veritable creator of the papal state by conferring on the pope the exarchate of Ravenna which he had wrested from Aistulf the king of the Lombards. Pippin took Septimania from the Arabs and after a stubborn war of nearly eight years duration (760-768) succeeded in taking Aquitaine from its duke Waifer. He also intervened in Germany where he forced the duke of Bavaria, Tassilo to become his vassal. In 763 however Tassilo abandoned Pippin during an expedition against Aquitaine. Pippin made several expeditions against the Saxons but failed to subdue them. He entered into relations with the Eastern Empire exchanging ambassadors with the emperor Constantine Copronymus. During Pippin's reign Frankish institutions underwent some modification. The Frankish assemblies, previously held in the month of March (*champs de mars*), but under Pippin deferred to May (*champs de mai*) came to be more numerous and served the king of the Franks as a means of receiving the gifts of his subjects and of promulgating his capitularies. At the head of the administration was placed the archchaplain, and an ecclesiastical chancellor was substituted for the ancient *referendarius*. Ecclesiastical reform was continued under Pippin. Bishop Chrodegang of Metz uniting the clergy of Metz in a common life and creating canons. Pippin died on Sept. 24, 768 at St. Denis leaving two sons Charles (Charlemagne) and

Carloman between whom he divided his kingdom.

**PIPRAWA**, a village on the Birdpur estate in the Basti district United Provinces India. It lies on the Uska Nepal road at mile 19.5 and about half a mile south of the boundary pillar numbered 44 on the frontier line between British and Nepalese territory. The village is celebrated as the site of the following discovery—

In 1806 interest having been aroused by the discovery only twelve miles away of the Buddha's birthplace (see LUMBINI) William Peppe then resident manager of the Birdpur estate opened a ruined stupa or burial mound situated at Piprawa. After digging through 18 ft of solid brickwork set in clay a massive stone coffer was found lying due magnetic north and south. Its dimensions were 4 ft 4 in by 2 ft 8½ in and 2 ft 2¼ in high and it contained five vessels: two vases, a bowl and a casket being made of steatite and the fifth also a bowl of crystal. All these vessels are beautifully worked; the crystal bowl especially with its fish-shaped cover handle being a work of art of high merit. The coffer is of fine hard sandstone of superior quality and has been hollowed out at the cost of vast labour and expense from a solid block of rock. Peppe calculated its weight and included at 137 lb. It is only the great solidity of this coffer which has preserved the contents. A cover of one of the vases was found dislodged and lying on the bottom of the stone coffer. As this coffer fits very well it must have required a quite violent shock to remove it. This was almost certainly the shock of an earthquake and the same shock probably caused the split in the stone lid of the coffer itself.

The vessels contained a dark dust, apparently disintegrated ashes, small pieces of bone and a number of small pieces of jewellery in gold, silver, white and red, cornelian, amethyst, topaz, garnet, coral and crystal. Most of these are perforated for mounting on threads or wires and had been no doubt originally connected together to form one or more of the elaborate girdles, necklaces and breast ornaments then worn by the women. On the bottom of the stone box there was similar dust, pieces of bone and jewellery and also remains of what had been vessels of wood.

An inscription ran round one of the steatite vases just below the lid. The words mean *This shrine for ashes of the Buddha the Exalted One is the pious work of the Sakya's his brethren associated with their sisters and their children and their wives*. The thirteen words in a local dialect of Pali are written in very ancient characters and are the oldest inscription as yet discovered in India.

The monument must have been of imposing appearance. The dome was of the shallow type, probably not more than about 35 ft high exclusive of the ornament on the summit. We have in bas-reliefs of the 3rd century representations of what these ornaments were like—small square erections like a shrine or small temple surmounted by a canopy called from its shape a T. They were then more than a third of the height of the dome itself. The total height of this Sakya stupa will therefore have been approximately a little under 50 ft. It was probably surrounded by a carved wooden railing but this has long since disappeared.

All such monuments hitherto discovered in India were put up in honour of some religious teacher and this is accepted as a monument put up over a portion of the ashes from the funeral pyre of Gotama the Buddha. The account of the death and cremation of the Buddha preserved in the Buddhist canon states that one eighth portion of the ashes was presented to the Sakya clan and that they built a *thupa* or memorial mound over it.

Mr. Peppe presented the coffer and vases with specimens of the jewellery to the museum at Calcutta where they still are. He also gave specimens of the trinkets to the Asiatic Society in London.

**PIPSISSEWA** (*Chimaphila umbellata*) called also prince pine a plant of the wintergreen family (Ivyaceae) flowering from June to August in deciduous wood in North America from Nova Scotia to British Columbia and southward to Georgia and California. It is found also in Europe and Asia. The flowers are fresh coloured or pinkish waxy five parted and grow in small or small groups on a three to ten inch stem. The leaves are dark green shining evergreen sharply toothed and appear in whorls or placed oppositely on the stem. The potted pipsissewa or potted wintergreen (*Chimaphila maculata*) occurs in small areas from Maine and Ontario to Minnesota and southward to Georgia and Missouri. Its leaves are dark green and mottled with white veins sharply toothed and tapering to narrow points.

**PIQUA** (pick-wa) a city of Miami county, Ohio U.S.A. situated on the Miami river and Federal highway 5 served by the Baltimore and Ohio the Pennsylvania and electric railways. Pop. (1900) 13,044 (95% native white) 1930 Federal census 16,009. It has grain elevators large quarries of blue limestone and many diversified manufacturing industries (making textiles stoves furniture blankets felts and various other articles) with an output in 1917 valued at \$18,713,031. On or near the site of Piqua was one of the principal villages of the Chillicothe division of the Shawnee tribe. A town called Washington was laid out in 1801, the present name (that of another division of the Shawnee tribe) was given in 1823. It was chartered as a city in 1830.

**PIQUET**, a game at cards probably a development of *ronfa* a game mentioned by Berni in 156. The Spanish name of the game was *cientos* (*centum* a hundred). Piquet was played in England under the name of *cent* probably as early as 1550.

The dealer deals 12 cards to his adversary and 12 to himself two at a time or three at a time. He then places the eight undealt cards called the stock face downwards on the table the top five being for the elder hand (non dealer) to take from first in exchange for his own. The players now look at their hands and *carte blanche* (see later) having been declared if there is one put out (without showing them) such cards as they deem advisable in order to improve their hands and take in an equivalent number from the stock. Each player must discard at least one card. If the elder hand discards less than the five he is entitled to he must state how many he leaves. He is entitled to look at the cards he leaves replacing them face downwards on the top of the stock. The younger hand then makes the exchange from the remainder of the stock. If the elder hand leaves any of the top five the younger may exchange as many as remain in the stock discarding an equal number. If the younger hand leaves any cards he announces the number left. He may look at the cards he leaves. If he looks at them he must show them to the elder hand after the elder has named the suit he will lead first or has led a card.

If the younger hand elects not to look at the cards left the elder cannot see them. The younger hand must make his election before he plays to the card first led or if so required after the dealer has named the suit he will first lead. Each player may examine his own discard at any time during the hand but he must keep it separate from his other cards.

The elder hand next declares what he has in his hand.

The point must be called first or the right to call it is lost. It is scored by the player who announces the suit of greatest strength valued thus ace 11 court cards 10 each other cards the number of pips on each. Thus if the elder hand's best suit is ace king knave nine eight he calls five cards. If the younger hand has no suit of five cards he says good. The elder hand then says 'in spades' or whatever the suit may be or shows his point face upwards. If the younger hand has a suit of more than five cards he says not good. If the younger hand has also five cards he says equal or what do they make? when the elder calls forty-eight (or 'making eight' short for forty eight) The younger must not inquire what the point makes unless he has an equal number of cards. If the younger hand's five cards make less than 48 he says good if exactly forty-eight he says 'equal' if more than forty-eight he says not good. The player whose point is good reckons one for each card of it, if the points

are equal neither player counts for point.

Sequences are usually called next the elder hand stating what his best sequence is and the younger saving good equal or not good as in the case of the point. Any three or more consecutive cards he takes up held in mind constitute a sequence. The order of the cards is as follows ace (hi he!) king queen knave ten nine eight seven six five four three two a. A sequence of three cards is called a tierce of four a quart of five a quint of six a sextet of seven a septet of eight a huitieme. A tierce of ace king queen is called a tierce major a tierce of king queen knave is called a tierce to a knave (and so on for the intermediate equer's according to the card which heads them) a tierce of nine eight seven is called a tierce minor. Sequences of four or more cards follow the same nomenclature e.g. ace king queen knave is a quart major knave ten nine eight is a quart to a knave and so on. A sequence of a greater number of cards is good against a sequence of a smaller number thus a quart minor is good against a tierce major. As between sequences containing the same number of cards the one headed by the highest card is good thus a quart to a queen is good against a quart to a knave. Only identical sequences can be equal. The player whose sequence is good reckons one for each card of it and ten in addition for quints or higher sequences. Thus a tierce counts three a quart four a quint fifteen a sextet six ten and so on. If the elder hand's sequence is good he names the suit or shows it face upwards. If the highest sequence (or the sequence first called) is good all lower sequences can be reckoned notwithstanding that the adversary has a sequence of intermediate value. For example A has a quart to a queen (good) and a tierce minor. He calls and reckons seven notwithstanding that B has a quart to a knave. B's quart counts nothing. If the highest sequence is equal neither player scores anything for sequence.

Quatorzes and trios are the next calls. Quatorze are composed of four aces four kings four queens four knaves or four tens in order of value trios of three of any of these. A quatorze if good reckons 14 a trio if good reckons three one that is good establishes any smaller quatorzes or trios in his hand.

When the elder hand has done calling he leads a card. Before playing to this card the younger hand reckons all that he has good stating of what cards his claims are composed or showing the cards claimed for. The elder hand leads any card he pleases the younger plays to it. The younger hand must follow suit if able otherwise he may play any card he thinks fit. It is not compulsory to win the trick. The leader counts one for each card led whether it wins the trick or not. If the second player wins the trick he also counts one. The winner of the last trick counts an additional one for the last card. The tricks are left face upwards in front of the player who wins them. They may be examined by either player.

If each player wins six tricks the cards are divided and there is no further score. If one player wins more than six tricks he wins the cards and adds ten to his score. If one player wins every trick he wins a *capot* and scores 40 for the cards instead of ten.

During the play of the hand a player is entitled to be informed as to any cards his adversary holds which he has reckoned as good or has declared to be equal. A player may require his adversary to exhibit any such cards. But if a player having played three cards of a *sixieme* declared as a quint is asked how many he has left he need only reply Two.

During the progress of the hand each player repeats aloud the amount of his score for the time being. At the end of the hand the points scored are recorded by each player. If there is any difference in the written scores a player's score of his own hand is deemed to be the correct one.

*Carte Blanche*—If either player has no king or queen or knave in the hand dealt him he holds *carte blanche* for which he scores ten. As soon as a player discovers he has a *carte blanche*, he must tell his adversary thus he usually does by saying 'discard for *carte blanche*'. The adverse discard is then made (as explained under discarding) after which the *carte blanche* is shown by dealing the cards face upwards on the table, they are then taken

back into the hand

*Pique*—If the elder hand scores in hand and play 30 or more before the younger hand counts anything in that deal he gains a *pique* for which he scores 30

*Repique*—If a player scores in hand alone 30 or more before his adversary reckons anything he gains a *repique* for which he adds 60 to his score. Equalities do not prevent piques or repiques. A player who has an equal point or sequence counts nothing for it. Therefore if notwithstanding the equality a player makes 30 in hand and play or in hand by scores which reckon in order before anything his adversary can count he gains a *pique* or a *repique*.

The order in which the scores accrue is of importance. For the sake of convenience the elder hand finishes his reckoning before the younger begins. The scores however whether made by the elder or younger hand are recordable in the following order: (1) *carte blanche* (2) point (3) sequences (4) quatorzes and trios (5) points made in play (6) the cards. This will often affect a *pique* or *repique*. Thus a *pique* can only be made by the elder hand as the one he reckons in play when he leads his first card counts before points subsequently made in play by the younger hand. The younger therefore cannot make 30 in hand and play before the elder scores one. But the one reckoned by the elder hand when he leads his first card does not prevent his being repiqued because scores made in hand have precedence of points made in play. The elder leads his first card and counts for it before the younger reckons simply as a convenient way of stating that he has nothing in hand which is good. Again say A has a quint (good) a tierce and a quatorze (good). He scores 32 in hand alone but if his point is not good he does not gain a *repique* because the younger hand's point is recordable in order before the sequences and quatorze. *Carte blanche* taking precedence of all other scores saves piques and repiques. It also counts towards piques and repiques. A *capot* does not count towards a *pique* as the *capot* is not made in play. It is added after the play of the hand is over. A player who reckons nothing that hand as a penalty is not piqued or repiqued if he holds any cards which but for the penalty would have reckoned before his adversary reached 30. The game most commonly played now (short game) consists of 4 hands only the last and first being doubled and 100 points added for the game.

See Cavendish *The Laws of Piquet and of Rubicon Piquet adopted by the Portland Club with a Treatise on the Game* (1888). Cavendish *Guide to Piquet* (1898). R. F. Foster *Hoyle's Games* (1928). (W. D. A.)

**PIRANDELLO, LUIGI** (1867–1936) Italian dramatist and novelist was born on June 28 1867 on a country estate near Girgenti (Sicily). He first went to Rome at the age of 19 staying there until 1891 when he went to Germany and graduated in philosophy at the University of Bonn. He subsequently returned to Rome and taught at the girls' high school until 1923. His first literary essays were in verse a volume entitled *Mal giocondo* published in 1889 followed by a poem *Pasqua di Gea* (1891) and *Elegie renane* (1895). Another Sicilian writer Luigi Capuana persuaded him to devote himself to fiction and in 1894 he published his first novel *L'esclusa* in which his somewhat bitter realism already finds expression. Besides the novel *Il turno* he began to publish short stories *Amori sen a amore* (1894) *Quando exo matto* (1903) *Befte della morte e della vita* (1902 1903) *Bianche e nere* (1904) etc. In 1904 his most celebrated novel *Il fu Mattia Pascal* appeared the story of a man who having shammed being dead tries in vain to begin his life anew in a different atmosphere and under another name. Other collections of short stories followed *Erma bifronte* (1906) *La Vita Nuda* (1910) *Terzetti* (1912). He set forth his artistic creed in two volumes entitled *Arte e scienza* (1908). In 1913 his novel *I vecchi e i giovani* describing the drama of Italian life after the Risorgimento was published in the *Rassegna contemporanea*. Other volumes of short stories appeared between 1914 and 1926 such as *La trappola* (1915) *Un cavallo nella luna* (1918) *Il carnevale dei morti* (1919), *Tu ridi* (1920) and another novel *Uno, nessuno e centomila* was published in the *Fiera letteraria*.

In 1900 he said of his own art—

I think that life is a very sad piece of buffoonery because we have in our lives without being able to know why wherefore or whence the need to deceive ourselves constantly by creating a reality (one for each and never the same for all) which from time to time is discovered to be vain and illusory. My art is full of bitter compassion for all those who deceive themselves but this compassion cannot fail to be followed by the ferocious derision of destiny which condemns man to deception.

This despairing outlook attained its most vigorous expression in Pirandello's plays. In his youth he had shown a certain contempt for the drama but in 1911 he was persuaded by the Sicilian playwright Nino Martoglio to dramatize one of his own short stories *La Morsa* as a one act piece. His first three act comedy *Se non così* (1911) was produced by Marco Pàra at Milan in 1913 and then many plays—dramas and comedies—of which the most celebrated are *Il berretto a sonagli* *Luola* (1917) *Così e se vi pare* (1918) *Luomo la bestia e la virtù* (1918) *Ma non è una cosa seria* (1918) *Come prima meglio di prima* (1920) *Sei per sonaggi in cerca d'autore* (1921) *L'imbacille Enrico IV* (1921) *Vestire gli ignudi* (1921) *La vita che ti diedi* *L'altro figlio* *Ciascuno a suo modo* *La sagra del signore della nave* *La giara*.

Pirandello's dramatic art was at first criticized for being too cerebral for not seeing life as it really is and for arbitrarily deforming it. The Roman critics first discovered the real meaning of Pirandello's ideology and the human sense of his plays. His main themes are the necessity and the vanity of illusion the multifarious appearances all of them unreal of what is presumed to be the truth man is not what he thinks he is but he is one no one and a hundred thousand accordingly as he appears to this person or to that and is always different from what he creates himself in his own mind. Hence the supreme catastrophe when a moral looking glass suddenly reveals to him the image of himself which others see and what he is to others. Most of Pirandello's plays deal with a lower middle class milieu peopled with clerks teachers lodging house keepers etc. from whose modest vicissitudes he draws conclusions of vast human significance. Typical is *Così e se vi pare* in which he proves that it is impossible to know the real truth. *Enrico IV* develops in a broader sense that is a drama in which we have a man who renounces his changing empty and vain existence to play the part of a mad man and pretends to believe himself an historical personage Henry IV. All this might be merely theatrical trickery if it were not seared by a deep anguish characterizing a philosophy which has destroyed all faith in the absolute in reality in any fixed limits outside individual personality.

Pirandello's plays have rapidly achieved success throughout Italy and abroad and have been translated into some 15 languages. In 1925 he created an art theatre of his own in Rome where new Italian and foreign plays are performed and in the summer of the same year he brought his company on a tour to England to produce his own plays in London (at the New Oxford theatre) to Paris Basle and 18 theatres in Germany. He died from pneumonia on Dec. 10 1936. (S. D. A.)

See W. Starke *Luigi Pirandello* (1926) and F. Pasini *Luigi Pirandello* (1927 bibl.).

**PIRANESI, GIOVANNI BATTISTA**, Italian engraver was born in the earlier half of the 18th century. He was a Venetian who settled in Rome where he devoted himself to engraving the ancient monuments. The explanatory texts engraved on many of his plates prove that his work was inspired by archaeological interest but he was more artist than archaeologist.

The most important of his publications are *Antichità Romana de Tempi della Repubblica* (1798) *Le Antichità Romane* 4 vols (1756) *Della magnificenza ed architettura de' Romani* (1761) and *Vedute di Roma* (135 plates engraved between 1748 and 1778 with two plates added later by F. Piranesi). He developed a powerful manner of etching. In his foregrounds the broad lines are strengthened with the graver. He achieves bold contrasts of tone which justify the large scale of his prints. Among his finest plates are the fanciful compositions in the *Opere Varie di Architettura* (1750) and in the *Carceri* (1750). He died in 1778.

**PIRANO**, a seaport of Istria, Italy in the province of Pola.

22 m SW of Trieste by rail Pop (1951) 6,511 (town) 1,485, (commune) It has picturesque Venetian walls and balconies. On the coast near are extensive salt pans. The Venetians dominated the fleet of Frederick Barbarossa off Pirano in 1181. It was incorporated into Venice in 1813 and was incorporated with Austria together with the rest of Trieste in 1813. It was the birthplace of the violinist Tartini. Near Pirano is the favourite seaside resort of Porto Rotondo.

**PIRATE and PIRACY** Sir J Fitzjames Stephen in his *Digest of Criminal Law* defined piracy as follows: Taking a ship on the High Seas or within the jurisdiction of the Lord High Admiral from the possession or control of those who are lawfully entitled to it and carrying away the ship itself or any of its goods, tackle, apparel or furniture under circumstances which would have amounted to robbery if the act had been done within the body of an English county. (Cf 4 G for Hon. Kong v. Kwok a Sing 1875 L.R. 5 P.C. 199) Piracy being a crime not against any particular State but against all mankind may be punished under international law in the competent court of any country where the offender may be found or into which he may be carried. But whilst the practice of nations give to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state) they may not be killed without trial except in battle. Those who surrender or are taken prisoners must be brought before the proper tribunal and dealt with according to law.

Following the sinking of merchant vessels at sight by German submarines in the World War by the Washington Treaties (1912) between the United States, the British Empire, France, Italy and Japan attacks upon and destruction of merchant vessels upon visit and search by any person in the service of any Power were declared acts of piracy and such persons may be brought to trial before the civil or military authorities of any Power within the jurisdiction of which he may be found. It was held by the Federal District Court of New York in the suits brought against the Cunard Steamship company for damages arising out of the sinking at sight of the *Lusitania* by a German submarine that such sinking was an illegal act. See *The Lusitania* (1918) 251 Fed. 715 *Scott's Cases* 784-90 (X).

## HISTORY

It is impossible to say at what period in the world's history piracy began. References to this form of robbery occur in early literature. It was rampant in the Mediterranean in the days of the Roman Republic and it is recorded that Julius Caesar when a young man fell into the clutches of a gang of sea robbers who held him prisoner until ransomed and that after his release he returned with some soldiers who captured his late gaolers and crucified the whole crew. Amongst the early pirates of which records still exist are the Phoenicians while there are numerous references to sea rovers in the *Odyssey*. Out of the dim North the Vikings (qv) are known to have come south to plunder the coasts of Britain, Ireland and France in A.D. 789 and onwards. For many centuries the north-east coast of Africa was the headquarters of the Barbary pirates (qv) or Moors as they were commonly called who had their chief strongholds at Algiers, Salé and Tripoli. From these harbours they sailed out to harry passing ships or plunder the opposite coast of Spain carrying back their Christian captives to sell as slaves. In spite of numerous punitive attacks these fierce sea robbers were not finally stamped out until 1830. All through the Tudor reigns piracy was rampant around the British Isles particularly in the south of Ireland and in the Scilly Isles where safe retreats existed for the pirate and where receivers of plunder were to be found willing to buy the goods that the pirate had to offer.

As in the case of the land thief the sea thief could not exist without a market for his ill-gotten goods. It would be useless for a pirate to seize a well-laden merchant ship if he had nowhere he could dispose of his prize. Sir William Monson in his book *Naval Tracts* records how he was sent in 1605 to search for pirates in the Shetlands and Hebrides. But it was in Ireland where he found what he looked for. At Broad Haven he met

with an Irish gentleman of the name of Cormac or Cormac whose house he describes being the well-head of all pirates. Here an Irishman lived in secret and trafficked with the pirate captain, many of whom were the lovers of his daughters.

As time became more difficult for the pirates in the home waters they moved further afield where they could practise their craft with less interference. Thus piracy spread to the East Indies and the coast of New England and eventually to the Red Sea and Madagascar. For many years the latter island was the headquarters of the pirates where they lived in security married their wives and reigned as petty kings. From here they were able to levy heavy toll on passing ships sailing between Europe and the East Indies.

The natural haunts of the pirates were in archipelagos and uncharted coasts and here at one time or another such places as the Greek Islands, the Indian Ocean, the coast of Calicut, the British Isles, Norway and the West Indies became their lurking place.

In England it did not until the 16th century piracy was not uncommon and it was no unusual event for the inhabitants of the Cinque Ports to sail forth in their small ships and plunder any passing vessel and on more than one occasion the fleet of New Romney attacked and plundered the ships of its rival Harwich.

**The West Indies**—The West Indies were well prepared for practical exploration both geographically and historically. Since the 16th century the buccaneers (qv) had preyed upon the Spaniards and there were innumerable hiding places, hidden bays in uncharted islands where pirates could meet in safety and divide the spoils and prepare for their next adventure. During the 17th century the island of Tortuga or Turtle Island off the coast of Hispaniola became a regular pirate republic. Good markets for stolen plunder were to be found on the New England coast and in Jamaica and at New Providence Island as well as in Ireland and certain places in the west of England.

Much of the piracy in the West Indies and America was the direct outcome of the Spanish policy of forbidding her colonists the right of trading with foreigners in spite of her inability to supply their needs herself. Naturally the Spanish Americans were only too eager to buy smuggled goods at very low prices and were not likely to be very particular to enquire where the goods came from. England and France also tried to insist on their colonists trading exclusively with themselves at their own prices which combined with the almost total lack of policing by the regular navies led to wholesale buying of smuggled merchandise procured by irregular methods. It was not until the reign of William III. about 1700 that workable laws were made for trying pirates and even then it was often difficult to get a jury to condemn a pirate who was looked upon as a public benefactor. Owing to the difficulty of policing the seas particularly in distant waters the custom arose in the reign of Charles I. and continued until that of George I. of granting free pardons to all pirates who would surrender themselves by a certain date. The result was that when things had become too warm for a pirate he would make his submission to the authorities and receive the royal pardon and as soon as ever his booty was spent resume his old practices. One of the greatest wholesale pardoning of pirates was carried out by Captain Woodes Rogers at New Providence in the Bahamas in 1718. At this time there were more than 2,000 freebooters entrenched in this pirate stronghold but Rogers dealt so successfully with them that almost all surrendered.

**Organization**—The ranks of the pirates were recruited from a type of seafaring man who disliked steady work with its small rewards and preferred a life of danger with a prospect of gaining sudden wealth. After every European war ships would be laid up and crews disbanded. There being no honest employment for all these sailors they were compelled by circumstances to take any employment at sea that offered itself and as often as not this consisted of signing on in a ship where no questions were asked and no wages paid but where every member of the crew took a share of any profits which might accrue from the voyage.

Very often when a pirate captured a merchant ship the crew of the latter were invited to join the pirates. Some would do so

willingly others only under compulsion. Most pirates when brought to trial pleaded that they had been compelled to join the pirates and had done so only to save their lives. It often happened that amongst the members of a captured crew there would be some sea artist as a particularly skilful ravigator was called and he would be compelled to sign on whether he wished to or not. A common source of piracy was the privateer, an armed ship that sailed under a letter of marque which was apt to drift into piracy when its legitimate prey was not forthcoming to supply the prize money which paid the wages of officers and crew. This fact was pointed out by Cotton Mather (*qv*) the New England divine in one of his hanging sermons delivered at Boston to condemned pirates. In one which he preached in 1704 called *A Brief Discourse occasioned by a Tragical Spectacle of a Number of Miserables under Sentence of Death for Piracy* he stated the Privateering Trade is usually carried on with an Unchristian Tempe and proves an Inlet into so much Debauchery and Iniquity.

The same view was expressed by Nelson when he declared that all privateers were no better than pirates although this wide accusation cannot be allowed to include such famous and patriotic privateers as Captain Fortunatus Wright or Commodore Walker. Many a shady privateer was little better than a pirate and the letter of marque under which he sailed a mere pretence as in the case of a pirate who plundered Spanish ships in the 17th century under a commission sold to him by the governor of a Danish West India island himself a reformed pirate. This document written in Danish proved when translated to entitle the holder to hunt for goats and wild pigs on the island of Hispaniola and nothing more.

The establishment of a pirate gang usually took one of two forms. The most usual was for a few ringleaders to plot a mutiny on board a merchant ship. At a prearranged signal the mutineers would seize the officers and kill them and any members of the crew who resisted and throw their bodies overboard.

But many a pirate who eventually rose high in his profession began in a very small way. Often a handful of desperate characters would steal a boat and row or sail along the coast by night until they surprised the crew of some small schooner and became masters of her. In this they would venture further afield until by cunning or force they got possession of a larger ship. The downfall of most pirates was brought about by their utter lack of discipline for unless the elected captain was a man of unusual strength of character as was the famous Captain Bartholomew Roberts he was unable to keep his crew in order and sooner or later disaster overtook them through careless navigation or at the hands of a better disciplined hostile ship.

One of the first formalities of a newly created pirate crew was the drawing up and signing of the ship's articles which would include such rules as the following taken from those of Captain John Phillips of the *Revenge*.

1 Every man shall obey civil Command the Captain shall have one full Share and a half in all Prizes the Master Carpenter Boat swain and Gunner shall have one Share and a quarter.

6 That Man that shall snap his Arms or smooke Tobacco in the Hold without a cap to his Pipe or carry a Candle lighted without a Lanthorn shall receive Moses's Law (that is 40 Stripes lacking one) on the bare Back.

9 If at any time you meet with a prudent Woman that Man that offers to meddle with her without her Consent shall suffer present Death.

Another matter, considered to be of great importance was the choice of a flag whose chief object was to 'strike terror into all beholders'. The favourite design was a skull and cross bones though sometimes a whole skeleton was depicted holding in one bony hand a rummer or glass of punch and in the other a sword or dagger. Whenever possible the pirates carried a surgeon, who was treated with a certain amount of respect.

**Famous Characters.**—The ordinary pirate was merely a criminal who lived for himself alone and lacked any sense of ambition other than to get rich quickly and must not be placed in the same category with the Vikings, who although sea robbers

and murderer worked in large and to a certain extent organized bands as did the Mediterranean pirates in Roman times who formed a highly organized brotherhood of desperadoes. The ordinary pirates boasted that they declared war upon the whole world and possessed no honour even amongst themselves.

A few of the most famous pirates may be briefly mentioned. Captain John Avery *alias* Every *alias* Brideman familiarly known as Lon Ben or the Arch Pirate was born at Plymouth about 1665, took to the sea and rose to mate in a merchant ship, headed a mutiny and was elected captain. He proved himself a daring pirate leader and after much success off the Guinea coast and in the West Indies sailed to the Red sea where he seized a rich ship of the Great Mogul reported to have on board 100,000 pieces of eight and the Mogul's young and lovely daughter. He took both to Madagascar where he settled down as a reigning monarch. In 1696 he was at Boston where he bribed the governor to allow him and his crew to land and dispose of their plunder. He died in poverty at Bideford after being tricked out of his ill-gotten gains by certain merchants of Bristol. Charles Johnson wrote a play called *The Successful Pyrate* which was acted at Drury Lane in 1713 and which was modelled on Avery's career.

Bartholomew Roberts was perhaps the greatest of all pirates. Born in Wales in 1682 he died fighting in 1722. He was credited with having taken over 400 ships during his career and was remarkable for his discipline for being a teetotaler and allowing no women or gambling aboard his ships.

Edward Teach *alias* Blackbeard a picturesque blackguard was killed on Nov. 22 1718 in a hand to hand combat with Lieut. Robert Maynard of H.M.S. *Pearl*.

Captain Misson a Frenchman of good family was unique in combining active piracy with socialistic ideals. He reigned for many years over a Utopian republic in Madagascar.

Two women pirates Anne Bonny and Mary Read deserve mention as both rose high in their ancient dual professions.

The famous Captain Kidd was no pirate at all but the victim or scapegoat of political intrigue.

With the peace of 1815 came a great increase in West Indian piracy which was assisted by the inability of the Spanish authorities to cope with the pirates while their colonies were seething with revolt. At last the British and American navies combined to root out the evil once and for all in the Atlantic although piracy lasted in the Greek islands until nearly 1850.

The end of piracy after centuries was brought about by public feeling backed up by the steam engine and telegraph. The last relic exists to day in China where a nest of troublesome pirates still carries on the old trade in spite of the navies of the foreign powers. The Chinese pirates ship themselves as ordinary coohee passengers on a coastal steamer and at a given signal produce revolvers and hold up the officers and crew and compel them to navigate the ship to their headquarters at Bias bay where the ship is plundered and officers and passengers held for ransom.

**BIBLIOGRAPHY.**—Mommensen's *History of Rome* Monson's *Naval Tracts in Churchill's Voyages* v. 5 (London 1744-46) and in *Navy Record Society* (1902) *State Trials* vols. xiii xiv xv (London 1812) Captain Charles Johnson's *General History of the Pyrates* (1724) gives full and accurate details of the lives activities and death of the most notorious pirates of the early 18th century and a second volume, published in London in 1726 does the same for the Madagascar pirates. It used to be said that Charles Johnson was inaccurate and unreliable but recent research has proved again and again that whoever he was he had first hand knowledge of his subject and is to be relied upon in almost every detail. F. C. Bradler *Piracy in the West Indies and its Suppression* (1923) G. F. Dow and J. H. Edmunds, *The Pirates of the New England Coast* (1630-1730). See also Publications of the Marine Research Society Salem Mass. 1923.

(P. Go)  
**PIRELLI AND CO** and SOCIETÀ ITALIANA PIRELLI OF MILANO Italy are now one of the largest industrial organisations throughout all Italy with a large number of international ramifications employing at the end of 1928 over 30,000 hands all over the world, specialising in the manufacture of electric cables, tyres of all descriptions and general india rubber and gutta percha goods. Founded in 1872 by Ing. Giovanni Battista Pirelli at present a member of the Italian Senate and president of the company they have gradually increased in

importance developing large factories in Italy (Milano Bicocca, Spezia and Vercurago) Spain (Villanueva y Geltru and Manresa) and in the Argentine (two factories in Buenos Aires).

Pirelli General Cable Works Ltd 144 Queen Victoria Street London E.C.4 with factories in Southampton and London. English and are among the most prominent British manufacturers of electric cables. Pirelli Ltd own a large factory of 100 acres at Burton on Trent manufacturing pneumatic and pneumatic and solid tyres these English factories employ British labour throughout.

Another Pirelli company owns large rubber plantations at Boenisan Isle of Java. Financial and commercial Pirelli companies operate from Barcelona, Brussels, Bucharest, Copenhagen and Paris and Pirelli agents are active in practically every commercial centre throughout the world. Pirelli also own or have controlling interests in cotton spinning and weaving mills, copper drawing mills and other branches of industry.

Among the lines in which the Pirelli companies specialise should be mentioned submarine telegraph cables laid across the Atlantic Ocean, high tension underground cables for abnormal working pressures installed in New York and Chicago, pneumatic semi-pneumatic and solid automobile motorcycle and bicycle tyres. (M.S.L.)

**PIRENNE, HENRI** (186–1933) Belgian historian was born at Verviers on Dec. 3, 1862. He first lectured at the University of Liege and was professor at the University of Ghent 1886–1930. His *Histoire de Belgique* of which seven volumes had appeared in 1932 completely revolutionized the current conceptions of Belgian history and nationality by showing how from the time of the Germanic invasions Flemings and Walloons were drawn together by community of tradition and economic interest. Pirenne's works on mediaeval cities and social conditions include *Les anciennes démocraties des Pays Bas* (1910 Eng. trans. 1915), *Recueil des documents relatifs à l'histoire de l'industrie drapière en Flandre* (with G. Espinas 4 vol. 1906–4) and *Mediaeval Cities: Their Origins and the Revival of Trade* (Princeton 1925). He was the first president of the Union Académique Internationale (190–23) and received many foreign honours.

**PIRKE ABOTH**, lit. Chapters of the Fathers, a collection of proverbs arranged chronologically and giving a catena of Jewish scholars. The treatise belongs to the 14th Order (*Neziqin*) of the Mishnah and deals with the history of tradition. Thus the so-called Oral Law (*Torah she be al Peh* Deut. iv 14 v 22–33 especially 31 and other passages) supplemented the Written Law (*Torah she be khethabk*). The Oral Law in Aboth is traced back from Moses through Joshua, the elders and Prophets to the Men of the Great Synagogue, a body the existence of which is now merely doubted but which was formerly denied categorically. Through Simon the Just (either Simeon grandson of Jaddua, High priest 310–91 B.C. or his grandson 219–199) and Antigonus of Socho, both survivors of the Great Synagogue, tradition is carried on by five pairs of teachers (*Zugoth* זוגות) to Hillel and Shammai (30 B.C.). Henceforward the sayings of their disciples and successors are given until chapter iv which concludes with Elazarhaq Qappar (end of 2nd cent. A.D.). Chapters iii and iv are not strictly chronological. Chapters v and vi are of later date. Chapter v combines historical, legendary and didactic elements, miracles are explained and a series of things, sayings and qualities are grouped numerically, e.g. ten *Maamaroth* or *Logot* are said to have created the world, vi is called the chapter of the acquisition of the Law and was probably added for liturgical purposes. Aboth is written in simple Hebrew. The aphorisms are of great intrinsic beauty and are of extreme historical importance not only for Judaism but for the environment of nascent Christianity. The chapters are read on different occasions, in most Jewish rites.

**BIBLIOGRAPHY**—Pirke Aboth may be studied in English in Singer's *Authorized Daily Prayer Book* pp. 184 sqq. I. Abrahams' Notes (pp. clxxvi of the annotated edition should be consulted). The reader is also referred (a) to the *Jew. Enc.* s.v. *Abot*, (b) *Abot* in *Encyclopaedia Judaica* vol. I, Berlin (1928), (c) R. Travers Herford's two editions (1) in R. H. Charles' *Apocrypha and Pseudepigrapha* vol. II (1913) and (2) publ. by *Jewish Inst. of Religion Press* (1925) on which see

S. B. M. in an article on pp. 3 sqq. of *Jewish Studies in Memoriam of I. L. B. H. H. H. H.* The older editions of C. Taylor and H. Strack are of great value.

**PIRMASENS**, a town of Germany in the Bavarian Pfalz, at the confluence of the Rhine and Moselle, 10 km. from Biebrich. It is one of the oldest towns in the Rhine region, who is said to have been the Chatti in the 5th century. It was a stronghold in the court of Hanau-Lichtenberg but passed to the Elector of Brandenburg in 1618. The principal industry is the production of beer and hoes but organ building and machines are also manufactured.

**PIRNA**, a town in the republic of Saxony on the left bank of the Elbe 11 m. above Dresden and on the railway to Boden, Buch and Prague. Pop. (1933) 35,000. Pirna originally a Slavonic settlement was for many years in the alternate possession of Bohemia and Meissen but it became permanently united with the latter and thus with Saxony in 1405. The most notable edifices are the Gothic parish church built in the 16th century and restored in 1890 and the old town hall. Excellent sandstone is found on both banks of the Elbe. There are manufactures of glass, machinery, cigars, pottery, slates and enamelled goods and cotton spinning and wood sawing. The Sonnenstein, a fortress on an eminence above the town, was erected in the 16th century.

**PIROGUE** or **PIRAGUA** (the French and Spanish forms respectively of a Caribbean word for this type of vessel, it has at various times taken many corrupt forms, e.g. *piragua*, *pettaugua*, *pettaoguar*) originally the native name of a vessel made by hollowing out the trunk of a tree, a dug-out, hence applied to many different developments of this type of vessel used in the West Indies and along the American coast. An early improvement was to split the dug-out into two sections and insert a flat bottom of planking to widen it; another form had a lee board, was decked in at either end and had two masts.

**PIRON, ALEXIS** (1689–1775), French epigrammatist and dramatist was born at Dijon on July 19, 1689. His father, Aime Piron, an apothecary, wrote verse in the Burgundian patois. Alexis began life as clerk and secretary to a banker and then studied law. In 1719 he went to Paris. In that year jealousy of the regular actors produced an edict restricting the Theatre de la Foire or licensed booths at fair times to a single character on the stage and Piron made a great success with a piece called *Arlequin Deucalion* representing Deucalion immediately after the Deluge. In 1728 he produced *Les Fils ingrats* (known later as *L'École des pères*) at the Comédie Française. He attempted tragedy unsuccessfully in *Calisthène* (1730), *Gustave Vasa* (1733) and *Fernand Cortès* (1744). Piron returned to comedy with *La Métromanie* (1738). His most intimate associates at this time were Mlle Quinault, the actress, and her friend Marie Thérèse Quenaudon, known as Mlle de Bar whom he married in 1741. He died on Jan. 21, 1773. His best title to remembrance lies in his epigrams. The burlesque epitaph on himself in which he ridicules the Academy—

Ci git Piron qui ne fut rien  
Pas même académicien

is well known. Grimm called him a machine à saillies.

Piron published his own theatrical works in 1758 and after his death his literary executor, Rigoley de Juvigny, published his *Oeuvres complètes*. M. Bonhomme produced a critical edition in 1859 completed by *Poésies choisies et pièces inédites* in 1879.

**PIROT**, a town of South Serbia, Yugoslavia. Pop. (1931) 11,380. It lies amid romantic scenery and is the seat of a prefecture and a tribunal. The inhabitants are engaged in the manufacture of jewellery, thin cloth, woollen braid and carpets. The latter, woven on hand looms by women and children, are its speciality and are noted for their excellent quality, designs and colouring. There are several schools, a large mosque and a curious old square leaning tower. The mediaeval fortress is believed to have been built on the site of the Roman fortress Quemedava on the military road from Old Naissus (Nish) to Philippopolis. Outside the town is an early modern entrenched camp. Pirot, which is strategically important, was captured by the Serbs in the Russo-Turkish War (1877–78) and was ceded to Serbia by the Treaty of Berlin (1878). In the war between Serbia and Bulgaria in 1885 Pirot was

occupied by the Bulgarians and held by them till peace was signed

**PIRRIE, WILLIAM JAMES**, 1ST VISCOUNT (1841-1941) British shipbuilder and engineer was born at Quebec on May 31 1847 and educated at Belfast Royal Academic Institution. In 1862 he entered the shipbuilding firm of Messrs Harland and Wolff of Belfast becoming partner in 1874 and later chairman. His success was particularly associated with the building by his firm of the White Star line steamships the first being launched in 1870. From 1896 to 1897 he was lord mayor of Belfast. In 1906 he was raised to the peerage as Baron Pirrie. In 1915 towards the close of the World War he was made controller general of merchant shipping. In 1911 on the King's visit to Belfast to inaugurate the new parliament of Northern Ireland he was created a viscount. He died on June 6 1941.

**PISA**, a town and archiepiscopal see of Tuscany, Italy, capital of the province of Pisa on the Arno 7 m from the sea and 49 m W of Florence by rail. Pop. (1931) 51,155 (town) 50,411 (commune). It retains its mediaeval walls 6½ m in circuit; the citadel now contains barracks. The cathedral, the baptistery and the famous leaning tower form a group by themselves at the north west corner of the town. The two former are built in black and white marble, a characteristic found in Pisan churches elsewhere also. (See *SARDINIA*.)

The architects of the cathedral were Buschetto and Rinaldo, both probably Pisans. The church is in plan a Latin cross 311½ ft long and 252 ft wide across the transepts inside. The nave 109 ft high has double the transepts, single vaulted aisles, and at the intersection of nave and transepts is a dome. The columns of the nave and side aisles are ancient. The west front is the finest part of the exterior; the range of arches running round the base is repeated by four open arcades. The three bronze doors were re-made after the fire of 1596; that of the south side (1180) is by Bonanno. The mosaics in the apse were designed by Cimabue and the splendid decagonal pulpit (restored in 1926

see *Per la ricostruzione del pergamino di Giovanni Pisano* 1936) is by Giovanni Pisano. The baptistery begun in 1153 is a circle 100 ft in diameter and is covered with a cone surmounted dome 190 ft high on which stands a statue of S. Ranieri. The lowest range of semicircular arches consists of 20 columns and the second of 60; and above this is a row of 18 windows in the same style separated by as many pilasters. In the interior which is supported by four pilasters and eight columns the most striking features are the octagonal font and the hexagonal pulpit erected in 1260 by Nicola Pisano. The campanile or leaning tower of Pisa begun by Bonanno in 1174 is round. The walls at the base are 13 ft thick and at the top about half as much—they are constructed throughout of marble. The base is surrounded by a range of semicircular arches supported by 15 columns and above this rise six arcades with 30 columns each. The eighth storey which contains the bells is of much smaller diameter than the rest of the tower and has only 12 columns. The height of the tower is 179 feet. The tower was 15½ ft out of the perpendicular when measured in 1829 and 16½ ft in 1910. There is no reason to suppose that the architects intended that the campanile should be built in an oblique position; it would appear to have assumed it while the work was still in progress. The foundations are not more than 10 ft deep and their circum-

THE LEANING TOWER OF PISA  
Begun in 1174 and completed in 1350 the campanile is 179 ft high and leans more than 16 ft out of the perpendicular.

ference only that of the tower. The Campo Santo lying to the north of the cathedral owes its origin to Archbishop Ubaldo (1100-1105) who made the spot peculiarly sacred by bringing shiploads of earth from Calvary. The building erected in the Italian Gothic style by Giovanni Pisano in 1278-83 is of special interest for its famous frescoes by various Tuscan artists including a Last Judgment by Francesco da Volterra after Orcagna (150-151). Benozzo Gozzoli (15th century) Old Testament scenes 1468-84 and also for the large collection of Roman sculptures which it contains. Other notable churches are S. Andrea S. Pierino S. Michele in Borgo (11th century) S. Sepolcro erected by Diotisalvi (c. 1150) S. Nicolo with a four storied tower (c. 1230) S. Caterina (15th century) S. Francesco (15th century) with frescoes by Taddeo Gaddi (in the adjacent monastery is the interesting museum and picture gallery) S. Maria della Spina an elegant little church of white marble (1325-9) and the Renaissance church of the Tuscan order of St. Stephen from plans by Vasari (after 1561) who also reconstructed the palace of the order.

The main streets of the older part of the town have porticoes. There are wide quays with fine buildings on each side of the Arno but the town as a whole is quiet owing much of its importance to its being the junction for Florence, Lucca and Volterra on the main line between Rome and Genoa. The university founded in 1338 had 1,096 students in 1925-26; it has a natural history and other museums and a botanical garden. There is also an engineering school (103 students), a veterinary institute (114 students) and an agricultural institute (109 students). In the vicinity are the royal villa and stud farm (horses and dromedaries) of San Rossore (the name is a corruption of Lussorio see *FORDUNGMANS*) and the mineral baths of San Giuliano alkaline ferruginous with temperature 91.4 to 105.8 F. At the mouth of the Arno joined to the city by a steam tramway (on the way is the old church of S. Piero in Grado) is the seaside resort of Marina di Pisa also known as Bocca d'Arno a well known centre for landscape painters. At Navacchio 5 m E of Pisa is a biscuit factory 4 m N of which is Calci and near it the large monastery of the Certosa di Pisa.

The ancient Pisaie on the right bank of the Arno was only 1 m from the sea the delta having increased since. It is believed to have been founded from Pisaie in Elis and is first mentioned in history as the place at which a Roman army from Sardinia landed in 225 B.C. Being situated on the coast road (Via Aemilia) it was important as a frontier fortress against Liguria for the fertility of its territory and its quarries and timber for shipbuilding. Scanty ruins of Roman baths exist near the modern Lucca gate on the north. The older town occupied the same site. (T.A.)

## HISTORY

Little is known of Pisa during the barbarian invasions but it is an ascertained fact that it was one of the first towns to assert its independence of Byzantine rule. During the first years of the Lombard rule the necessity of defending the Italian coast from the attacks of the Byzantines was favourable to the development of the Pisan navy.

**Early Wars**—In 1003 we find records of a war between Pisa and Lucca which according to Muratori was the first waged between Italian cities in the middle ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. Numerous legends and fables of the old chroniclers serve to attest the importance of Pisa in those days. The Saracens repeatedly attacked the town but were repulsed and the Pisans themselves assumed the offensive in Calabria, Sicily and even in Africa. In 1015 a memorable expedition was undertaken by the united forces of Pisa and Genoa against Mogahid better known in the Italian chronicles as Mugeto whom they drove from Sardinia. Again invading the island he was again attacked and defeated by the same adversaries leaving a brother and son or as some authorities aver a wife and son prisoners in their hands. Sardinia continued to be governed by native judges who were like petty sovereigns but were now subject to the sway of Pisa. This was

the primary cause of the jealousy of the Genoese and of the wars afterwards made by them upon Pisa. Meanwhile the Pisans flourished more and more and continued hostilities against the Saracens. In 1066 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di mare*) which in 1053 were approved by Gregory VII and in 1081 confirmed by a patent from the emperor Henry IV. The oldest of Pisan statutes still extant is the *Breve dei consoli di mare* of 1166.

**Commercial Prosperity**—In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem and derived many commercial advantages from it. For within a short time they had banks, consuls, warehouses and privileges of all kinds in every Eastern port. Thus while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party and filled the highest offices of the republic which in the 11th century rose to great power both on sea and land by its wars with the Lucchese, Genoese and Muslims. In the years 1113 and 1115 it achieved a still greater enterprise. The Pisan fleet of 300 sail commanded by the archbishop Pietro Moriconi attacked the Balearic Islands where as many as 6000 Christians were said to be held captive by the Muslims and returned loaded with spoil and with a multitude of Christian and Muslim prisoners. The former were set at liberty or ransomed and among the latter was the last descendant of the reigning dynasty. Immediately afterwards the 14 years war with Genoa broke out. The two republics contested the dominion of the sea and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan Church proved sufficient cause for the war which went on from 1118 to 1135. Then Innocent II transferred the supremacy over part of Corsica to the Genoese Church and compensated Pisa by grants in Sardinia and elsewhere. Accordingly to gratify the pope and the emperor Lothar II the Pisans entered Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples and twice attacked and pillaged Amalfi in 1135 and 1137 with such effect that the town never regained its prosperity. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Muslims (1187) the Pisans and Genoese again met in conflict in the East and it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063 and its consecration took place in 1118; the baptistry was begun in 1152 and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists who gave new life to Italian architecture as they afterwards renewed the art of sculpture.

#### RIVALRY WITH FLORENCE AND GENOA

The chief authority was still vested in the nobles who both in Pisa and in Sardinia exercised almost sovereign power. They formed the real strength of the republic and kept it faithful to the empire and the Ghibelline party. The Guelph and popular element which constituted the force and prosperity of Florence was hostile to Pisa and led to its downfall. Owing to the political and commercial interests binding Florence to the Roman court, the Guelph element naturally prevailed there while growth of its trade and commerce necessarily compelled that republic to encroach on waters subject to Pisan rule. And although Pisa had hitherto been able to oppose a vigorous resistance to Genoa and Lucca it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence which broke out in 1222 to a ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog—which merely shows that there were already so many general

and permanent reasons for war that no special cause needed to provoke it. In 1183 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garagnana and at the same time they dispatched 5 galleys to assist Frederick II in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia and war was interrupted down to 1199 when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca and all the Guelph cities of Tuscany against its Ghibelline rival; the pope had excommunicated Frederick II and all his adherents and as a crowning disaster the death of Frederick in 1195 proved a moral blow to the Italian Ghibelline cause. Nevertheless the Pisans were undaunted. Summoning Siena, Pistoia and the Florentine exiles to their aid they boldly faced their foe but were defeated in 1244. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now 12 elders (*aniani*) besides the podestà; there was a captain of the people and there was a general council as well as a senate of 40 members. The rout of the Tuscan Guelphs on the field of Montaperti (1260) restored the fortunes of Pisa. But the battle of Benevento (1266) where Manfred fell and the rout of Tagliacozzo (1268) sealing the ruin of the house of Hohenstaufen in Italy and the triumph of that of Anjou were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Guelph and popular side to which the more ambitious nobles began to adhere for the furtherance of personal aims the aristocratic Ghibelline party was rapidly losing ground. At this time Count Ugolino della Gherardesca had become the virtual head of the republic and in order to preserve its independence and his own sway inclined to the Guelph and the popular party in spite of the Ghibelline traditions of his race. He was supported by his kinsman Giovanni Visconti, judge of Gallura in Sardinia, but almost all the other great families vowed eternal hatred against him and proclaimed him a traitor. In 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city and laid waste its surrounding territories. In 1280 the Pisans were compelled to agree to very grievous terms—to exempt Florentine merchandise from all harbour dues to yield certain strongholds to Lucca and to permit the return of Count Ugolino. Thus the count again became a powerful leader in Pisa. Visconti however was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes as if to measure their strength and prepare for a final effort. On Aug. 6, 1284, at the great battle of Meloria, 2 Pisan galleys engaged 88 Genoese and half the Pisan fleet was destroyed. The chroniclers speak of 5000 killed and 11000 prisoners and although these figures must be exaggerated so great was the number of captives taken by the Genoese as to give rise to the saying—To see Pisa you must now go to Genoa. This defeat crushed the power of Pisa. She had lost her dominion over the sea and the Tuscan Guelphs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters he sought to confirm his own power by making terms with the Florentines by yielding certain castles to Lucca and by neglecting to conclude negotiations with the Genoese for the release of the prisoners lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop Ruggieri having put himself at the head of the nobles was elected podestà by the Lanfranchi, Sismondi and Gualandi and a section of the popular party. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After

a day's fighting (July 1188) the count his two sons and his two grandsons were captured in the palazzo del popolo (or town hall) and cast into a tower belonging to the Gualandi and known as the Tower of the Seven Streets. Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri the Florentine patriot and foe of Rome were naturally in favour of the victims of an aristocratic prelature opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa and a few of their vessels succeeded in forcing an entry into the Pisan port blocked it with sunken boats and seized its towers. In 1193 they secured a profitable peace. They and the other members of the Guelph league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia and throughout the island of Elba were exempted from every tax. They likewise received a ransom of 160,000 florins for their Pisan prisoners.

In 1312 the arrival of the Emperor Henry VII gladdened the hearts of the Pisans but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa and Uguccione della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people and thus became virtual lord of the city. As a Ghibelline chief of valour and renown he was able to restore the military prestige of the Pisans who under his command captured Lucca and defeated the Florentines at Montecatini on Aug. 29 1315. In 1316 however he was expelled in an outburst of popular fury. But Pisa's freedom was forever lost. Uguccione della Faggiuola was succeeded by other lords or tyrants of whom the most renowned was Castruccio Castracane a political and military adventurer of much the same stamp as Uguccione himself. With the help of Louis the Bavarian Castruccio became lord of Lucca and Pisa and was victorious over the Florentines but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords or petty tyrants rose to power in turn during this period of civil discord but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them forever—but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese Mantuan and Paduan allies they gave battle to their rivals put them to rout at Altopascio (Oct. 2) and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio and attacking the Pisan harbour carried off its chains bore them in triumph to Florence and suspended them in front of the baptistery where they remained until 1348. Then in pledge of the brotherhood of all Italian cities they were given back to Pisa and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV and afterwards Giovan Galeazzo Visconti known as the count of Virtù determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction headed by the Gherardesca with the Bergolini led by the Gambacorti had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti the ruler of the moment was treacherously assassinated by Jacopo d'Appiano who succeeded him as tyrant of Pisa and bequeathed the state to his son Gherardo. The latter a man of inferior ability and daring sold Pisa to the count of Virtù, receiving in exchange 200,000 florins Piombino and the islands of Elba Pianosa and Monte Cristo. Thus in 1399 Visconti took possession of Pisa and left it to his natural son Gabriele Maria Visconti, who was afterwards expelled from its gates. But even in this century of disaster the Pisans continued to encourage not only commerce, but also the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Nic-

cola and Giovanni Pisano by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration and the celebrated frescoes attributed to Orcagna (qv) were painted on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note and the labour of ornamentation was only discontinued in 1404.

**The Victory of Florence**—Meanwhile in 1406 the Florentine made another attack upon Pisa besieging it simultaneously by sea and land. Owing to the starving condition of its defenders and aided by the treachery of Giovanni Gambacorti they entered the city in triumph on Oct. 9 and sought to crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty. Such were the orders sent by the Ten of War to the representatives of the Florentine government in Pisa and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner course. In 1477 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars and leaving only a few chairs of letters and philosophy in Florence compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII made his descent into Italy in 1494 and came to Sarzana on his way to Tuscany he was welcomed by the Pisans with the greatest demonstrations of joy. And although that monarch was ostensibly the friend of Florence they did not hesitate even in his presence to assert their own independence and casting the Florentine emblem the *Marzocco* into the Arno made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault and what was worse yearly laid waste their territories and destroyed all their crops. Soderini who was perpetual gonfalonier of Florence and Machiavelli the secretary of the Ten urged on the war. In 1509 Florence encamped her forces on three sides of the distressed city which at last reduced to extremity by famine was compelled to surrender on June 8 1509. Thenceforth the Florentines remained lords of Pisa. But now mainly owing to the efforts of Soderini and Machiavelli the conquerors showed great magnanimity. They brought with them large stores of provisions which were freely distributed to all endeavoured to succour the suffering populace in every way and gave other assistance to the wealthier classes. Nevertheless emigration continued even on a larger scale than in 1406 and the real history of Pisa may be said to have ended. In Naples in Palermo in all parts of Italy Switzerland and the south of France we still find the names of Pisan families who quitted their beloved home at that time. The Florentines immediately built a new citadel and this was a great bitterness to the Pisans. The Medici however remained well disposed towards the city. Leo X. was an active patron of the university but it again declined after his death. The grand duke Cosimo I. a genuine statesman not only restored the university but instituted the *uffizio dei fossi* or drainage office for the reclamation of marsh lands and founded the knighthood of St. Stephen. This order played a noble part in the protection of Tuscan commerce by fighting the Barbary pirates and establishing the prestige of the grand ducal navy (see MEDICI). Under the succeeding Medici Pisa's fortunes steadily declined. Ferdinand I initiated a few public works there and above all restored the cathedral which had been partly destroyed by fire in 1595. These dreary times are brightened by one glorious name—that of Galileo Galilei.

B. Supino *Pisa in l'Italia artistica* series (P.V.I.V.)

**PISA, COUNCIL OF** (1409) The great schism of the 14th century had already lasted thirty years and the error which had been made to restore unity within the Church by the mutual excommunication of the two rival pontiffs had been in vain when in the spring of 1408 the state of affairs being desperate the idea arose of assembling a council to effect a union without the cooperation of the popes. The initiative came from the cardinals who had one after the other seceded either from Gregory XII or Benedict XIII. The day after the opening of the council proceedings were started against the two popes who it was agreed were to be eliminated. In order to depose them with some show of legality it was necessary as a preliminary to convict them of heresy and it began to be seen that their tenacity of power and the ruses by which they evaded the necessity of abdicating however harmful might be their consequence did not in themselves constitute a clearly defined heresy. On the 26th of June 1409 was read the definitive sentence that as heretics and therefore separated from the Church Pedro de Luna (Benedict XIII) and Angelo Corrarion (Gregory XII) were *ipso facto* deposed from any office they must not be obeyed nor assisted nor harboured.

In order to complete their task the cardinals present at Pisa authorized by delegation of the council shut themselves up in conclave and elected one of their number Peter Philarges cardinal of Milan as the new pope who assumed the name of Alexander V. They had hoped to save the Church but unfortunately the result of their efforts generous as they were was that the schism increased in bitterness and that instead of the unity for which the Church craved three popes continued to flourish. Both the deposed pontiffs protested against the legality of the council of Pisa each had numerous partisans and the thesis constructed rather to meet the exigencies of the case which attributed to a synod assembled by the cardinals the right of constituting itself judge of a sovereign pontiff was far from being established. The council was proceeding to occupy itself with reform when it was dissolved by Alexander V (August 1409).

**PISAN, CHRISTINE DE** (1364–c. 1450) French poet of Italian birth was born at Venice in 1364. When she was four years old she was brought to her father a councillor of the Venetian Republic in Paris where he held office as astrologer to Charles V. At fifteen Christine married Étienne du Castel who became Charles's notary and secretary. After the king's death in 1380 her father lost his appointment and died soon after and when Christine's husband died in 1389 she found herself without a protector and with three children depending on her. This determined her to have recourse to letters as a means of livelihood. Her first ballads were written to the memory of her husband and as love poems were the fashion she continued to write others—*lais virelais rondeaux* and *jeux à vendre*—though she took the precaution to assure her readers (*Cent ballades* No. 50) that they were merely exercises. In 1399 she began to study the Latin poets and between that time and 1405 as she herself declares she composed some fifteen important works chiefly in prose besides minor pieces.

The earl of Salisbury who was in Paris on the occasion of the marriage of Richard II with Isabella of France (1396) took her elder son Jean du Castel (b. 1384) and reared him as his own. The boy after Salisbury's death (1400) being received by Philip of Burgundy at whose desire Christine wrote *Le Livre des faits et bonnes moeurs du sage roy Charles* (1405) valuable as a first hand picture of Charles V and his court. Her *Mutation de fortune* in which she finds room for a great deal of history and

philosophy was presented to the same patron on New Year's Day 1404. It does not seem an introduction of great autobiographical interest. In *Le Livre de la vie* (1405) she tells her own story by way of defence against those who objected to her presence at a moralist Henry IV of England desired her to make his court her home and he received a like invitation from Galeazzo Visconti, but of this she never took power to remain in France where he moved he favoured Charles VI the dukes of Berry and Burgundy the duche of Bourbon and others.

Christine was a champion of her own sex. In her *De la rose* (140) she criticises an error of the members of which find the relief to be a defence of the honour of women. Her *Épître au dieu d'amour* (1399) is a defence of women against the attack of Jean de Meun and initiated a prolonged dispute with two great choirs of her time Jean de Meun (d. 1415) and Constance Col who undertook the defence of the *Roman de la rose*. Christine wrote about 140 two books for women *La Cité des dames* and *Le Livre des trois vertus* or *Le Tresor de la cité des dames*. She was devoted to her adopted country. During the civil war she wrote a *Lamentation* (1410) and a *Li re de la pain* (1411–1413) but after the disasters of the campaign of Agincourt she retired to a convent. We have no more of her work until 1419 when she broke her silence to write a song in honour of Joan of Arc. Of the circumstances of her death nothing is known but it probably took place about this time.

Her poems were edited by Maurice Roy for the *Société des anciens Textes français* (1886 etc.) and her *Li re du chemin du long estude* by Puchel (Berlin 188). There are monographs by Raymond Thomas (Paris 1838) E. M. D. Robineau (Saint Omer 1882) and Friedrich Koch (Goslar 1885). It is possible that Jean Castel who was chronicler of France under Louis XI was Christine's grand son. Hoccleve imitated her *Épître au dieu d'amour* in his *Letter of Cupid* (*Chaucerian and other Pieces* ed. W. W. Skeet 1891). A translation of her *Épître d'Othée* was made (c. 1440) by Stephen Scrope for his stepfather Sir John Fastolf and is preserved in a MS. at Longleat. This was edited (1904) for the Roxburghe Club by W. G. F. Warner as *The Epistle of Othée to Hector or the Boke of Knighthode. The Moral Proverbs of Christine de Pise* translated by Earl Rivers was printed in 1418 by Caxton who himself translated by order of Henry VII her *Li re des fait d'armes et de chevalerie* a treatise on the art of war based chiefly on Vegetius. Her *Cité des dames* was translated by Brian Anslay (London 151).

**PISANO, ANDREA** (c. 1300–1348) Italian sculptor was born about 1200 and first learned the trade of a goldsmith. His style was influenced to some extent by Giovanni Pisano. His chief works were executed at Florence and the formation of his mature style was due rather to Giotto than to his earlier master. Of the three world-famed bronze doors of the Florentine baptistery the earliest one—that on the south side—was the work of Andrea. He spent many years on it and it was finally set up in 1336. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues and the rest scenes from the life of the Baptist. At the death of Giotto in 1337 Andrea was appointed architect of the campanile and built the two stories of niches above the work of Giotto. Of the beautiful panel reliefs which decorate the campanile those representing *The Crane Weaving* *Daedalus Navigation* *Hercules Agriculture* *Theatre* and *Medicine* display the style of Andrea Pisano. The *duomo* contains the chief of Andrea's other Florentine works in marble. In 1347 he was appointed architect in the *duomo* of Orvieto which had already been designed and begun by Lorenzo Maitani. The date of his death must have been shortly before 1349.

See M. Raymond *La Sculpture Florentine* (Florence 1897)

**PISANO, GIOVANNI** (c. 1249–after 1314) Italian architect and sculptor was the son of Niccolò Pisano. He developed and extended into other parts of Italy the renaissance of sculpture initiated by his father. He spent the first part of his life as a pupil and fellow worker of Niccolò and appears as his collaborator at the fountain of the great piazza at Perugia. Between 1278 and 1283 he was employed on the cloister which surrounds the Campo Santo at Pisa. In 1284 Giovanni was appointed *capo maestro* of the new cathedral at Siena. He began the magni

The date on the door 1330 refers to the original wax model.

ficient façade. His design however was modified by the architects who succeeded him. From 1295 to 1301 he was employed on the pulpit of San Andrea at Pisa. Then followed the pulpit of the cathedral at Pisa completed in 1311. It was taken to pieces some two hundred years later but fragments are to be seen at Pisa and in the Berlin museum. The figures for the tomb of the Empress Margaret now in the Palazzo Bianco at Genoa were executed soon after the Empress' death in 1311. A number of statues of The Virgin and Child have been attributed to him on stylistic evidence. Among these the three most important are at Prato in the Campo Santo, Pisa, and in the Arena chapel at Padua. The Cathedral of Pisa has a fine figure of the Madonna carved in ivory. Giovanni's early work was inspired by his father Niccolò. Later his figures and draperies displayed the expressive flow of lines appertaining to the Gothic style. Like the work of most stonemasons in mediaeval times his sculpture forms part of an architectural design. The subject matter of his carving was dictated by the liturgy of the church and his interpretations are imbued with deep religious feeling.

**PISANO, NICCOLÒ** (c. 1230–c. 1278) Italian sculptor and architect settled at Pisa. A document among the archives of the Sienese Cathedral calls him son of Petrus de Apulia and most modern writers believe that he not only was a native of the province of Apulia in southern Italy but also that he gained there his early instruction in the arts of sculpture and architecture. Except through his work little is known of the history of Niccolò's life. In 1259 as an incised inscription records he finished the marble pulpit for the Pisan baptistery; this is his most important early work and is entirely classical in spirit.

It is a high hexagon on semicircular arches with trefoil cusps supported by seven marble columns three of which rest on white marble lions. In design it presents a combination of Gothic forms with classical details. Five of the sides of the main hexagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Crucifixion and the Last Judgment. These are all works of the highest beauty and a wonderful advance on anything of the sort that had been produced by Niccolò's predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity and the stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccolò's study of the antique is most apparent. The veiled and diademed figure of the Virgin Mother seated on a throne recalls the Roman Juno; the head of Joseph behind her might be that of Vulcan while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing and kneeling figures of the Magi.

The beautiful relief of the Deposition from the Cross in the tympanum over a side door at San Martino at Lucca was probably Niccolò's most important work. Then followed the Arca di San Domenico in the church at Bologna consecrated to that saint. This work was completed in 1267 in collaboration with the Dominican Fra Guglielmo. The most magnificent of Niccolò's works is the great pulpit in Siena cathedral. It is much larger than that at Pisa being an octagon on cusped arches and columns. The contract for this work (1266) discloses the names of Niccolò's assistants—Arnolfo (di Cambio), Donato and Lapo—besides his son Giovanni. In the reliefs of this pulpit can be traced the influence of the great Gothic sculptors of France. They mark the beginning of a new epoch in the history of Italian sculpture: classical repose is sacrificed for expression of religious emotions.

Niccolò's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of three basins rising one above another each with sculptured decoration; it was begun in 1274 and completed with the co-operation of Niccolò's son Giovanni and of Arnolfo di Cambio. Niccolò appears also to have had knowledge of archi-

tecture for when he signed the contract for the pulpit in Siena he stipulated that he might go to Pisa four times a year to attend consultations about the building of the cathedral and baptistery. Many important buildings are ascribed to him by Vasari without corroboration. In 1278 Niccolò is mentioned for the last time as working on the fountain in Perugia. The first record of his death occurs in Sienese archives under the date Aug. 30, 1287.

**PISANO, VITTORE** (1397–1455) commonly called PISANELLO, Italian medallist and painter was the son of a Pisan father called Bartolommeo and a Veronese mother. He was one of the leading artists of his age and enjoyed great celebrity during his lifetime. Guarino, a distinguished humanist, sings his praises in lines such as these: "Great is the renown that comes to Verona from the excellence of your work and our age has produced you to be numbered with the great sculptors and painters of antiquity." We know nothing concerning Pisanello's artistic education. Vasari who likes to derive all great art from Florence states that he studied under Andrea del Castagno in Florence. But he was more probably trained in Verona in the traditions of Altichiero. About 1422 he worked in conjunction with Gentile Fabriano in the great council hall of the doge's palace in Venice. During their stay in Venice the two artists exercised a great influence on the development of Venetian art. Pisanello was much favoured by the princes and potentates of Italy. There is evidence that he worked at various times at Ferrara, Mantua, Milan, Pavia, Naples, Rome, Venice and Verona. He was well received at the courts of his patrons; he designed their costumes, the patterns of the material they used, the harness for their horses besides painting their portraits and Madonna pictures.

Unfortunately only very few of his paintings have survived. These are the fresco of The Annunciation in S. Fermo at Verona and the fresco painted on the arch of the Pellegrini chapel in S. Anastasia in the same city representing St. George Mounting his Horse. Three easel pictures may be singled out as representative of the master: the Miraculous Stag appearing to St. Eustace in the National Gallery, London; the portrait of a princess of the house of Este in the Louvre; and the portrait at the gallery in Bergamo of Lionello d'Este who was one of the artist's chief patrons and admirers. These panels are carefully finished to the minutest detail and are beautifully drawn. The Louvre possesses in the Vallardi book a number of delicate and spirited pen drawings by Pisanello. These detailed studies of nature in which animals figure very largely seem to have been his great delight and display the powers of an extraordinary draughtsman. But it is for his medals and plaques that Pisanello is best known. Although he was not as was at one time asserted the inventor of the medal, it was he who initiated this form of art as one of the most characteristic productions of the Renaissance. Pisanello's earliest medal was probably that of the Greek emperor John VII. Paleologos dated about 1438–39.

**PISAURUM** (mod. Pesaro *q.v.*) an ancient town of Umbria on the Via Flaminia 26 m. from Ariminum and 8 from Fanum Fortunae. A Roman colony was founded here in 184 B.C. at the mouth of the river Pisaurus (mod. Foglia; the sea has since receded about half a mile). It was destroyed by the Goths in 539 and restored by Belisarius in 545.

**PISCES**, the Fishes, in astronomy the twelfth sign of the zodiac represented by two fishes tied together by their tails and denoted by the symbol ♓. In Greek legend Aphrodite and Eros while on the banks of the Euphrates were surprised by Typhon and sought safety by jumping into the water where they were changed into two fishes. This fable however as in many other similar cases is probably nothing more than an adaptation of an older Egyptian tale. The constellation contains only faint stars.

without any striking grouping

*Piscis au tralis* or *Austrinus* the southern n h is a constellation of the southern hemisphere. It contains Fornax and a star of the first magnitude

*Piscis claus* the flying fish is a constellation introduced by John Bayer in 1603. The name is now abbreviated to *Pisces*

**PISCICULTURE** The species of food fish that can be kept successfully in ponds throughout their lives from egg to adult are exceedingly limited in number. The most bred of gold fish and top minnow (*Cyprinodont*) are tame like lampreys and the carp is an example of food fishes capable of similar domestication. In the United States the eastern brook trout and the black bass are almost as fully domesticated. Various other food fishes both marine and fresh water can be kept in pond for longer or shorter periods but refuse to breed while in other cases the fry obtained from captive breeders will not develop. Consequently there are two main types of pisciculture (1) the rearing in confinement to an edible stage of the young of domesticated breeders (2) the stocking of natural waters with eggs or fry from captured adults

**Fish rearing**—Of the first type of pisciculture there are several examples of commercial importance in the cultivation of fresh water fishes. The pond culture of carp is important in China and Germany but in England it has long fallen out of use and is not likely to be resumed so long as other fresh water fish can be obtained and distributed so readily as is now the case. In the United States pond culture of carp has been practically discontinued because of the prejudice of native Americans against the fish and because of its great increase in natural waters which now afford a large commercial yield. In Germany on the other hand intensive methods have been applied to pond culture with remarkable results in recent years

In the United States some species of trout and char have become so thoroughly domesticated that many commercial trout hatcheries have been established some of them with a score of ponds heavily stocked with eastern brook trout (*Salvelinus fontinalis*) sorted into different ponds according to size and fed usually on slaughter house offal in addition to such natural food as they may obtain. Under this system the trout grow twice or three times as fast as the wild ones a growth of from 7 to 11 in during the first year being no exception. Some of the male fish are killed and sold before they are sexually mature but most of the fish are kept until they reach sexual maturity in the second fall of their life at the age of 20 months and are then stripped and sold immediately thereafter

Next in order of importance are the North American basses and sunfishes (family *Centrarchidae*) all of which make nests. The most important members of the family are the largemouth (*Aplodes salmoides*) and smallmouth (*Micropterus dolomieu*) black bass which are propagated in large numbers of State national and private ponds. Artificial nest boxes with bottoms covered with material suitable for the species are placed in the ponds the fish spawn in them and the male guards the nests and schools of fry. The schools of young usually numbering several thousand to the nest are transferred to rearing ponds and fed on Japanese *Daphnia* raised in small separate ponds and on other food. Young bass are usually planted as fingerlings 3 or 4 in long or as yearlings. They could be raised for the market but the cost would be prohibitive. In addition to the bass seven species of sunfishes are cultivated in the United States by similar but simpler methods

In the lagoons of the Adriatic and the salt marshes of various parts of France examples of the cultivation of salt water fish are to be found analogous to the pond culture of fresh waters. Here as in ancient Greece and Rome it is the practice to admit young fish from the sea by sluices into artificial enclosures or viviers and to keep them there until they are large enough to be used. An interesting modification of this method of cultivation has been introduced into Denmark. The entrances to the inner lagoons of the Limfjord are naturally blocked against the immigration of flatfish by dense growths of sea grass (*Zostera*) although the outer lagoons are annually invaded by large numbers

of mullet from the North sea. The fishermen of the district consequently combined to destroy the expenses of transplanting large numbers of mullet from the outer water to the inner lagoon where the war found a more fertile field than in their native habitat. The experiment has been known by Dr. Petersen to be due to the fact that the mullet coupled with the lack of overcrowding of the main fish. This transplantation of small mullet to Denmark has been annually repeated for many years with no necessary and a profitable contribution to the catch of mullet to a small charge upon the Government funds

A result of the international North Sea fishery investigations is a report proposed to apply the same principle for the development of the deep sea fishery in the neighbourhood of the Dogger Bank. Experiment with labelled plaice carried out in 1904 by the Marine Biological Association showed that mullet plaice transplanted to the Dogger Bank in prime grew three or four times as rapidly as those on the inshore grounds and the same result with insignificant variations has been obtained by similar experiments in later years. (See *Reports* of the Ministry of Agriculture and Fisheries cited at the end.) In this case the deep water round the Dogger Bank act as a barrier to the emigration of the mullet from the shores. It has consequently been proposed that the small plaice should be transported in millions to the bank by well vessels every spring. It is claimed as further result of the experiments that from May to October the young fish would be practically free on the shallow part of the bank from the risk of premature capture by trawlers and that the increased value of the fish consequent upon their phenomenal growth rate would greatly exceed the cost of transplantation. The development of seining on the Dogger Bank since 1919 has probably increased the risk of premature capture but satisfactory information on this point is lacking. In the experiments made by the English Ministry of Fisheries the transplanted fish retaken by seiners amounted to about 50% of the total recaptured in 1919 and 1923 but the actual months are not stated

Not unlike the work on plaice is the rescue work carried on in the United States chiefly by the Bureau of Fisheries but also by the States of Minnesota Wisconsin Iowa and Illinois. With the recession of the waters of the Mississippi river after spring freshets many fishes become land locked in temporary ponds or sloughs. By removing them to permanent waters they are saved from death due to drying of the ponds. In 1906 the Bureau of Fisheries seined about 150 000 000 impounded fish and returned them to open waters and similar work is undertaken each year

In France and Japan the methods of oyster and mussel culture are similar in principle to those just described. A breeding stock is maintained to supply the ground or the collectors with spat and the latter when sufficiently grown is then transplanted to the most favourable feeding grounds care being taken to avoid the local overcrowding which is so commonly observed among shell fish under natural conditions

**Fish hatching**—The second and more familiar type of pisciculture is that known as fish hatching with which must be associated the various methods of artificial propagation. Fertilization of the spawn is easily effected by stripping the eggs from the female into a moistened pan and immediately adding the milt of the male by the same process (the dry or Russian method). Water is next repeatedly added and poured off to wash the milt from the eggs which soon swell and harden so that they may be transferred to the hatching apparatus without injury. Although simple floating hatching boxes may often be used in natural waters for large scale operations hatcheries are constructed and the type of apparatus employed in them depends on the eggs to be hatched. For the smaller and lighter semi buoyant or demersal eggs such as those of whitefish (*Coregonus*) shad (*Alosa sapidissima*) etc. tall glass jars are used provided with a central inlet pipe through which water reaches the bottom of the jar and flows upward through the eggs to escape at the top. The dead eggs float and are removed by siphoning. The jars are grouped into batteries each of which may be merely a number of jars set on a table and supplied with water from a pipe above them as in hatching shad. For hatching whitefish and pike perch

eggs a battery may consist of more than 200 jars arranged in four superimposed tiers on two sides of a complicated system of wooden troughs which serve to convey water to and from them.

For hatching the larger and heavier demersal eggs of trout and salmon primitive apparatus still in use in parts of Europe consists of long wooden troughs in which the eggs lie on gravel in running water. In more modern hatcheries in order to economize space and utilize the water supply to the best advantage the troughs are divided into boxes by transverse partitions and the boxes are filled with trays or baskets of egg. The partitions are so constructed that the water which flows along the trough from box to box is given an upward or downward movement through the eggs in each box. For hatching trout eggs ten shallow wooden trays with bottoms of wire gauze each supporting a single layer of eggs are stacked in each box covered by an empty tray and latched down by a cross bar. A trough of five boxes carries from 500 000 to 750 000 eggs. The trout fry remain on the trays until a week or ten days before the yolk sac is absorbed and are then planted or transferred to rearing ponds. Four Pacific salmon baskets of wire screen are half filled with eggs (about 30 000) and one basket is placed in each box with the top projecting above the water so that no eggs can escape. The newly hatched fry fall through the meshes in the bottom of the basket and remain on the bottom of the box until the heavy yolk is so far absorbed that they are able to swim upward. They may be then planted or held and fed in artificial ponds near the hatcheries to be planted when a year or more old.

For the buoyant eggs of cod use is commonly made of the McDonald or tidal hatching box which is so constructed that a jet of water gives a rotary motion to the eggs while an intermittent siphon causes the water in the box to rise and fall at regular intervals so that the rotating eggs are carried up and down much as they would be by the waves of the open sea.

The hatching of the eggs whether of fresh or salt water fishes presents no serious difficulties if suitable apparatus is employed but the rearing of fry to an advanced stage without serious losses is less easy and in the case of sea fishes with pelagic eggs the larvae of which are exceedingly small and tender is still an unsolved problem although recent work carried out at the Plymouth laboratory of the Marine Biological Association in England is at least promising. It has been found possible to grow pure cultures of various diatoms and by feeding these to various larvae kept in sterilized sea water great successes have been attained. In fresh water culture there may be little advantage in artificial hatching unless it is followed by a successful period of rearing. Thus the Howieton Fishery Company (England) recommended their customers to stock their streams either with unhatched ova sown in redds or with three months old fry. Their experience is that there is no half way house between ova sown in redds and three months old fry. Younger fry may do but only when ova would do as well and at half the cost. In marine hatcheries on the other hand it is the invariable practice to hatch the eggs although the fry have to be put into the sea at the most critical period of their lives in an environment which teems with predacious enemies.

Some of the advances made in the United States in recent years in the cultivation of fish and shell fish are shown by the examples which follow. They suggest the importance of a detailed knowledge of the life history of the forms to be cultivated and the advantages of rearing to a suitable stage.

Decline in the Pacific salmon fishery led to the establishment of hatcheries until in 1921 there were 90 such establishments maintained by the United States by the individual States and by British Columbia. But in spite of the great hatchery output the fishery continued to decline alarmingly in certain localities. This apparent failure of the hatcheries to rehabilitate the fisheries led the authorities of the United States and British Columbia to promote a co-operative and detailed study of the life history of the Pacific salmon in the hope that this would reveal better means of artificial propagation or enable fisheries restrictions to be intelligently applied, while in 1924 by act of Congress, full control of the Alaskan fisheries was placed in the hands of the

Department of Commerce and has since been exercised by its Bureau of Fisheries.

There are five species of Pacific salmon (*Oncorhynchus*) all of which ascend from the sea into the rivers to spawn and are captured in commercial nets on the upward journey. Unlike the Atlantic salmon they invariably die after spawning but the young hatched from their eggs return to the sea after a longer or shorter stay in fresh water. Investigations of the past ten years have added many important details of the life history. The method of investigation consists in part in marking the young by removal of some of the fin releasing them in fresh water at various ages and in various places and recovering the marked fish when they return from the sea to fresh water to spawn. In part it consists of the microscopic study of the markings of the scales of returning adults. From these the age rate of growth and period of time spent in fresh water may be determined. From these investigations it is now known that the fry may begin their return to the sea soon after hatching (pink and chum salmon) or may remain in fresh water for a year (silver salmon) or from one to four years (red salmon) or as in the chinook they may either start for the sea soon after hatching or when 2 or 18 months old. The age at return to fresh water also varies. In the pink it is invariably two years in the chum from two to five or six years in the silver three years in the red three to seven years in the chinook two to seven or eight years.

The salmon of each species almost invariably come back to spawn in the stream or lake in which they were hatched (parent stream). The most important discovery of recent years is this confirmation of the parent stream theory with the resultant conception of each species as made up of numerous self contained colonies or races of interbreeding individuals. It results that if commercial fishing or other obstruction of a stream prevents so many individuals of any race from returning to their home spawning ground that an adequate breeding stock is not maintained that race is depleted or disappears and its racial ground is not afterward colonized by other races. It is then essential that commercial fishing be so conducted as to permit the escapement to the spawning ground of enough breeding fish of each colony to maintain that colony. In Alaska the U.S. Bureau of Fisheries now requires a spawning escapement of 50%. This regulation was first imposed in 1924 and in 1926 the run of pink salmon a two year fish was the largest ever known. How large the spawning escapement must be to maintain a racial population in any locality is not yet definitely known. Actual counts made under the direction of Dr. Gilbert have shown that in the Karluk river Alaska, three red salmon returned in 1926 for each parent fish of the 1921 spawning escapement. This ratio does not include the fish of the 1921 hatch that returned in earlier years or those still to return. If the proportion should prove to hold for all seasons an escapement of less than one third would serve to maintain the race.

From studies made on the return of young salmon marked and released in fresh water evidence is accumulating that artificial propagation may be made effective. It has been found that marked fingerlings of the Alaskan sockeye or red salmon released in the Columbia river in the fall of their first year fail to return but if released in the spring of their second year they return. Success does not necessarily depend merely on the release of great numbers of large and vigorous fingerlings but on their release at the right age, the age at which they naturally begin their seaward voyage. It has been found further that since each tributary (Columbia river) supports a separate colony it is inadvisable to transfer fingerlings from one tributary to another. Different racial groups start their spawning migrations at different times and each starts at such a time as to bring it to the spawning grounds when conditions there are suitable for laying of the eggs and development of the young of that race. If fingerlings are released on an alien ground they will return as adults to it but they may then find the conditions on it unsuited to them at the time of their return. By releasing the fry or fingerlings of each race on its home ground and at the right age better results may be expected from hatchery operations than have been reached up

to this time. Thus in an experiment on the Columbia river the number of returning adult recaptured after having been marked as fingerlings and released on their home ground when of suitable age was 30 times that necessary to produce the eggs from which they came (Holmes). Increased runs of Pacific salmon are also reported by Canadian officials as the result of hatchery operations in the Frazer river.

In the United States many of the natural oyster beds have been so exploited that they have disappeared and others are greatly depleted. The great size of the beds, the high cost of labour and the relatively low price of the product make the method of pond culture currently employed in France and Japan impracticable. Culture consists at present wholly of rehabilitating the beds in natural waters and increasing their number (planted beds). About half the 30,000,000 bu. of oysters marketed annually are now obtained from planted beds and in the New England States about 90% are from that source.

It has long been known that fertilized eggs could be obtained by cutting open oysters and stripping the apparently ripe milt and eggs from them, but recently oysters have been induced to spawn naturally in tanks of sea water by permitting the temperature to rise to about 70° F and in this way better results have been obtained. But for artificial culture large numbers of the minute larval oysters must be raised to the fixed or spat stage. This has been hitherto impossible owing to the difficulty of retaining them in tanks while supplying them with running water. Until they are several days old they pass readily through felt or the finest silk bolting cloth. A new filtering material known as *filtros* has now proved entirely satisfactory and several lots of larvae have been reared to the spat stage by investigators of the U.S. Bureau of Fisheries. Seed oysters for planting have become increasingly scarce and costly, but if the method referred to becomes a part of commercial oyster culture they may be produced in quantity at a cost much below that of collecting them from the beds.

In the United States the supply of the species of fresh water mussels from which pearl buttons are made has declined in recent years with the result that much work has been done on methods of cultivating these forms. The larvae (*glochidia*) after expulsion from the gills of the female mussel become parasitic on the gills of fish from which they draw their nourishment and from which they fall after transforming into young mussels. In the earlier attempts to increase the mussel supply fish artificially inoculated with glochidia were released into natural waters and not only fish captured for the purpose but great numbers of rescued fish (see above) were used. In 1906 fish rescued and released by the U.S. Bureau of Fisheries had been inoculated with nearly 3,000,000,000 glochidia taken from about 40,000,000 mussels. Later experiments showed that the inoculated fish could be held in troughs until the young mussels dropped from them. The latter were then cared for during the first season of their growth. But the number of glochidia that can be safely carried by a single fish is limited and the inflammation caused by over infestation results in many deaths. Hence a method was sought of rearing the glochidia without permitting their attachment to a fish host. Although the inoculation of both fish to be held captive and of those to be released is still practised it recently has been found that the glochidia may be reared to young mussels in an artificial medium which supplies the nourishment normally drawn from the fish host and makes the use of the latter unnecessary. With perfection of the technique it is practically certain that young mussels will soon be raised and distributed in large numbers without employing fish hosts.

In the lobster (*Homarus*) the eggs are carried attached to the appendages of the lower surface of the abdomen of the female and average 30,000 in lobsters 13 in long. The larvae hatched from the eggs pass through a remarkable series of transformations at successive moults. During the first four stages they are minute and free swimming and subject to destruction by storms and countless enemies, but at the close of the fourth stage or in the fifth they become ambulatory, descend to the bottom and show an ability to protect themselves. One lobster at this stage

is worth many thousands in the first (Herrick). Owing to the hard outer shell it is not possible to strip the lobster and cultivation therefore consists in rearing the naturally hatched young through the helpless stage, during which the ambulatory bottom stage is capable of self protection. The most successful method is that devised by Mead and his co-worker and first used at Wickford, R.I., under the name of the Rhode Island commission is of inland fishery.

The unit apparatus is a wooden box 10 ft. square and 4 ft. deep with screened opening in the bottom and on two opposite sides near the top. The boxes in groups of six float with tops above water supported by four 3 ft. long anchored in the case in a protected situation where the water is of suitable quality. Near the bottom of each box a horizontal two-bladed propeller with a radius of about 1 ft. is made to revolve by means of suitable shafts and gearing driven by a naphtha motor or other power source. The propeller draws water through the screened opening in the bottom of the box and forces it upward in a spiral course to its escape through the side openings. Egg bearing or berried lobsters are placed in one of the boxes just before the eggs are ready to hatch and as hatching takes place the fry are carried toward the top of the box and kept in suspension as though in the open sea. For rearing the fry are transferred to other boxes where they secure natural food from the entering sea water but are also supplied abundantly with other food preferably chopped cooked beer which is kept in suspension by the current and retained in the box by the screens. During the six to eight weeks season 500,000 fourths may be reared in 24 boxes. The method is believed to produce about 80 times as many fourths as are necessary to maintain the normal population of adults and heavy captures are therefore possible without depleting the grounds.

**Objects and Utility of Fish hatcheries.**—The earlier advocates of artificial propagation and fish hatching seem to have been under the impression that the thousands of fry resulting from a single act of artificial propagation meant a corresponding increase in the numbers of edible fish when once they had been deposited in suitable waters and also that artificial fertilization ensured a greater proportion of fertilized eggs than the natural process. For the first proposition there is no evidence while the second proposition is now discredited. The advantage of artificial hatching lies in protecting the unhatched eggs from the very large destruction to which they are subjected under natural conditions. But it is recognized that the great fertility of fishes is nature's provision to meet a high mortality—greater in sea fishes with minute pelagic eggs—a condition which entails a greater delicacy of their larvae at the time of hatching. Artificially propagated eggs and fry must submit *after planting* to the same mortality as the other eggs and fry around them. Consequently it is useless to plant out eggs or fry unless in numbers sufficiently great to increase appreciably the stock of eggs and fry of the same age already existing. It is this combined always with the suitability of the external conditions which accounts for the success of the best known experiments of American pisciculturists.

The shad fisheries of the streams of the east coast of the United States declined on the whole 14% from 1896 to 1923 and are now totally destroyed in many streams in spite of plants of fry which reached the large total of 400,000,000 in 1898 but owing to the difficulty of obtaining breeding fish has since then in general declined to about 35,000,000 in 1923. We have still little knowledge of the habits and life history of the shad of the extent and direction of its migrations. Its ascent of streams has been often impeded by dams and pollution has doubtless adversely affected the spawning migration, vitiated the breeding grounds and destroyed the fry. Artificial hatching has failed to maintain the species in Atlantic waters under these handicaps and in the face of intensive fishing. Under more normal physical conditions and with fuller knowledge of the life history of the species it might be effective in these waters as it begins to be in the case of the Pacific salmon. The artificially propagated eggs of the shad from the eastern rivers of the United States were planted in those of California where the species did not naturally

occur. The conditions were suitable and the species became at once acclimatized and has increased greatly. Similarly reservoirs and streams can be stocked with various kinds of fish not previously present. But in the case of indigenous species the breeding stock must be very seriously reduced before the addition of the eggs or fry of a few score or hundreds of fish can appreciably increase it.

In the case of sea fishes it is becoming increasingly recognized that the millions of cod fry which are annually turned out of the American Newfoundland and Norwegian hatcheries are but an insignificant fraction of the billions of fry naturally produced. A single female cod liberates according to its size from one to five million eggs in a single season. Yet the annual output of fry from each of these hatcheries rarely exceeds 100,000,000, i.e. the natural product of a few hundred cod at most. In Britain marine hatcheries have been established by the Fishery Board for Scotland in the Bay of Nigg near Aberdeen by the Lancashire Sea Fisheries Committee at Peel and by the Government of the Isle of Man at Port Erin. These establishments have been principally devoted to the hatching of the eggs of plaice. But again the maximum output of fry from any one of these establishments has not exceeded 50,000,000 in any single year. As a single female plaice produces about 200,000 eggs per annum this output does not exceed the natural produce of a few hundred fish. Under these circumstances the probable utility of the operations could be admitted only if the fry were sedentary and could be planted in suitable localities where young fish were naturally scarce. But the fry drift with the currents as helplessly as the eggs and the *a priori* objections to the utility of the operations have in no case been met by satisfactory evidence of tangible results.

The Scottish Fishery Board carried out a large scale experiment from 1896 to 1908 which was very illuminating (Fulton 6th Report). They attempted to measure the density of young plaice on the beaches of Loch Fyne during six years when plaice fry were liberated in the loch and a similar period when none were added. From 1896 to 1901 the quantities of fry added were 4, 21, 19, 16, 30 and 51 millions annually; the number of eggs naturally present in the loch being estimated at nearly 500,000,000 in 1898 (Williamson 17th Report). Although the figures of young plaice on the beaches yielded an average density which was twice as great in the first period as in the second (88.40 per hour) there was little or no correspondence from year to year between the density of young fish and the number of fry planted. The highest record corresponded with the year of maximum output of fry (1901) but the next highest occurred in 1905 when no fry were planted and the third occurred in the first year (1896) when the number planted was negligible (4,000,000). Assuming (which is not certain) that the coincidence in 1901 was significant it nevertheless appears that the natural fluctuations in the number of young plaice were unaffected by the hatching operations except in the one year when the number of fry liberated exceeded 50,000,000 and thus formed an appreciable proportion (10%) of the number estimated to be naturally present. Even these numbers do not provide Loch Fyne with a regular plaice fishery.

In the United States the utility of the cod hatching operations has in the past been often asserted by representatives of the Bureau of Fisheries but practically the only evidence adduced is the occasional appearance of unusual numbers of cod in the neighbourhood. It has not been established that the fluctuations in the local cod fisheries bear any relation to the extent of the hatching operations while the earlier reports of the commissioner of fisheries contain evidence that similar fluctuations occurred before the hatching of Fish Commission Cod began.

The situation is much the same with regard to the operations of the Newfoundland hatcheries at Dildo (See Fryer Reports x-xii of H.M. inspectors of sea fisheries E and W).

The most exact investigations bearing upon this problem are those undertaken in Norway in connection with the cod hatching operations at Arendal under Captain Dannevig. Four fjords were selected on the south coast of Norway in proximity to the hatchery and the usual number of fry (10 to 30 millions) was planted in the spring in alternate fjords leaving the intermediate fjords

unplanted. The relative number of young cod in the various fjords was then carefully investigated throughout the succeeding summer and autumn months. It was found that there was no relation between the abundance of young fish and the presence or absence of artificial fry. In 1904 33,000,000 fry were planted in Sondelfjord and young fish were exceptionally abundant in the following autumn (three times as abundant as in 1903 when no fry were planted). But their abundance was equally striking in other fjords in which no fry had been planted while in 1905 all the fjords were deficient in young cod whether they had been planted with fry from the hatchery or not. (For a summary of these investigations see *Papers on Artificial Fish Hatching in Norway* by Captain Dannevig and Dahl Report of the Lancashire Sea Fisheries laboratory for 1906 Liverpool 1907).

It would seem clear that the attempts hitherto made to increase the supply of sea fish by artificial hatching alone have been unsuccessful. The experience gained has doubtless not been wasted but the direction to be taken by future work is plain. The energy and money devoted to hatching operations should be diverted to discover a means of rearing on a large scale the just hatched fry of the more sedentary species to a sturdy adolescence. When that has been done it will be possible to deposit the young fish in suitable localities on a large scale with a reasonable prospect of influencing the local abundance of the species of fish in question. The increase of the supply of the migratory marine species such as the cod depends on a more complete knowledge of habits, life histories and migrations. With this knowledge in hand these fisheries may be maintained or increased either through regulation or by artificial propagation or by both means until it is in hand the effect of artificial propagation cannot be estimated.

In the smaller bodies of fresh water there is no doubt of the effectiveness of hatchery operations but in the Great Lakes of North America there is no dependable evidence of their value. Official statistics studied by P. Reighard in 1908 showed on their face a correlation between the average intensity of the plants of whitefish fry in certain regions of the Great Lakes during three five year periods from 1892 to 1906 and the average catch of whitefish for the same periods. Intensive planting was found to be correlated with an increased fishery output and was recommended. On the other hand Dr. Koelz who has an intimate knowledge of the fisheries operations of the Great Lakes is doubtful of the value of statistics based largely on reports of interested parties the fishermen. He points out further that the planted fry are a very small fraction of those presumably hatched naturally (0.35% in Lake Huron in 1900).

The decline in the coregonine fisheries of the Great Lakes is further evidence of the inadequacy of present hatchery methods. Whether the whitefish (*Coregonus clupeaformis*) has declined is uncertain but the bluefin of Lake Superior and the bloater of Lake Ontario (both forms of *Leucichthys nigripinnus*) have become commercially extinct and in 1925 the important Lake Erie herring (*L. artedii*) suddenly gave out and has not since regained its commercial importance. The bluefin and bloater were never propagated artificially but hundreds of millions of Lake Erie herring eggs have been hatched annually. It appears from these three cases that for some unknown reason when the breeding stock of a gregarious fresh water species has been reduced below a certain numerical minimum the decrease continues. In the case of the bloater it has led to extinction and the important Lake Erie herring in spite of extensive hatchery operations appears now to be faced with extinction. The value of artificial hatching as hitherto carried out in the Great Lakes is now questioned in the United States for the reasons stated above and in Canada the abolition of hatcheries has been advocated by Prof. Knight of the biological board of Canada. It is probable that the life histories and migrations of many species approach in intricacy those of the Pacific salmon with its numerous independent self-sustaining colonies or races. Until these intricacies are resolved by prolonged research and hatchery operations adjusted to them it is felt that artificial propagation is, in most cases, carried on

blindly and that success depends on chance

**PISCINA**, originally a fish pond later any artificial pool or tank such as a bathing or swimming pool Ecclesiastically the term is used for the stone basin with a drain emptying upon virgin soil in which the utensils of the mass are cleaned and ritual ablutions performed In mediaeval churches especially in England piscine are most frequently in the chancel close to the altar and often set in recessed arched niches of great beauty

**PISEK**, a town of Czechoslovakia on the Otava a tributary of the Vltava in one of the cereal and cattle basins of south Bohemia and on a main line from Prague to Budejovice Linz and Vienna Pop (1917) 16306

**PISEMSKY, ALEXEY FEOFI LACTOVICH** (1820-1881) Russian novelist was born on his father's estate in the province of Kostroma on March 2 1820 the son of a major who had risen from the ranks From the gymnasium of Kostroma he passed through Moscow university and spent over 20 years in the government service His first novel *Boyarstchina* was forbidden by the censor His principal novels are *Tyufyak* (A Muff) 1850 *Tsyacha Dush* (A Thousand Souls) 1862 and *V balomuchenoie morye* (A Troubled Sea) giving a picture of the excited state of Russian society about the year 1862 His *Gorkaya sudbina* (A Bitter Fate) depicting the dark sides of the Russian peasantry obtained for him the Ouvaroff prize He died at Moscow on Feb 2 1881 Pisemsky was a realist and took an objective view of the unrest among the intelligentsia which made him very unpopular in Moscow literary society His best work is his description of the life of the common people He learnt to know them thoroughly when investigating conditions in the Russian interior

A PISCINA IN EXETER CATHEDRAL

**PISHIN**, a district of Baluchistan It consists of a large plain surrounded on three sides by hills which formerly belonged to Afghanistan but was ceded to the British by the treaty of Gandamak in 1893 The main route of the road leading from Sialkot to the Punjab frontier district to Kandahar and is intersected by the Sialkot railway For administrative purposes it is included in the district of Quetta Pishin pop (1931) 14541

#### PISHPEK SEE PESHANZE

**PISIDIA**, the name given to a country in the south of Asia Minor immediately north of Pamphylia by which it was separated from the Mediterranean while it was bounded on the north by Phrygia on the east by Lycia and Cilicia and on the west and southwest by Lycia and a part of Phrygia It was a rugged and mountainous district occupied by wild and lawless races of mountaineers The Pisidians are not mentioned by Herodotus either among the nations that were subdued by Croesus or among those that furnished contingents to the army of Xerxes They turned a pretext to the younger Cyrus for leaving the army with which he designed to subvert his brother's throne while he pretended to put down the Pisidians who were continually harassing the neighbouring nations by their lawless forays (Xen Anab 1.1.11 etc) They assume a more prominent part in the history of Alexander the Great to whose march through their country they opposed a determined resistance In Strabo's time they had passed under the Roman dominion though still governed by their own petty chiefs

Notwithstanding its rugged and mountainous character Pisidia contained in ancient times several considerable towns the ruins of which exist The most important are Termessus near the frontier of Lycia a strong fortress in a position of great natural strength and commanding one of the principal passes into Pamphylia Cremna another mountain fortress north of the preceding impending over the valley of the Cestrus Sagalassus a little farther north a large town in a strong position the ruins of which are among the most remarkable in Asia Minor and Antioch known for distinction sake as Antioch of Pisidia and celebrated for the visit of St Paul This was situated in the extreme north east of the district immediately on the frontier of Phrygia between Lake Egerdir and the range of the Sultan Dag and was reckoned in the Greek and earlier Roman period e.g. by Strabo as a city of Phrygia

We have no clue to the ethnic character and relations of the Pisidians except that we learn from Strabo that they were distinct from the neighbouring Solymi who were probably a Semitic race but we find mention at an early period in these mountain districts of various other tribes as the Cabali Milyans etc of all which as well as the neighbouring Isaurians and Lycaonians the origin is wholly unknown and in the absence of monuments of their languages must remain so

**BIBLIOGRAPHY**—J S Speurth *Epigraphical Journey in Asia Minor* (1888) C Lanckorowski *Les villes de la Pamphytie et de la Pisidie* (1890-93) Sir W M Ramsay *History and Art of Eastern Provinces of the Roman Empire* (1906) *Cities of St Paul* (1907)

**PISO**, the name of a distinguished Roman plebeian family of the Calpurnian gens which continued in existence till the end of the 2nd century AD Nearly fifty of its members were prominent in Roman history but the following deserve mention

1 **LUCIUS CALPURNIUS PISO CAESONINUS** Roman statesman was the father in law of Julius Caesar In 58 BC when consul he and his colleague Aulus Gabinius entered into a compact with P Clodius with the object of getting Cicero out of the way Piso's reward was the province of Macedonia which he administered from 57 to the beginning of 55 when he was recalled perhaps in consequence of the violent attack made upon him by Cicero in the senate in his speech *De provincis consularibus* On his return Piso addressed the senate in his defence and Cicero replied with the speech *In Pisonem* Piso issued a pamphlet by way of rejoinder and there the matter dropped Cicero being afraid to bring the father in law of Caesar to trial At the outbreak of the civil war Piso offered his services as mediator but when Caesar marched upon Rome he left the city by way of protest He did not however definitely declare for Pompey but

remained neutral. After the murder of Caesar he insisted on the provisions of his will being carried out and for a time opposed Antony. Subsequently he became one of his supporters and is mentioned as taking part in an embassy to Antony's camp at Mutina.

2 **LUCIUS CALPURNIUS PISO** surnamed *Frugi* (the worthy) Roman statesman and historian was tribune in 149 B.C. He is known chiefly for his *lex Calpurnia repetundarum* which started the system of establishing regular courts for the trial of particular offences in place of the old system of special tribunals being appointed for each case. As praetor (136) and consul (133) Piso fought against the slaves in Sicily.

See **ANALISTS** C. Cichorius in Paulys *Wissowa's Realencyclopädie* (1897) vol. III pt. 1. H. Peter *Historiae romanorum reliquiae* (180) vol. 1. (1904).

3 **GNAEUS CALPURNIUS PISO** Roman statesman was consul in 7 B.C. and subsequently governor of Spain and proconsul of Africa. In A.D. 17 Tiberius appointed him governor of Syria with secret instructions to thwart Germanicus to whom the eastern provinces had been assigned. The indignation of the people at the death of Germanicus and the suspicion that Piso had poisoned him forced Tiberius to order an investigation. Piso committed suicide though it was rumoured that Tiberius fearing incriminating disclosures had put him to death.

See H. Schiller *Geschichte der römischen Kaiserzeit* (1883) vol. 1.

**PISSARRO CAMILLE** (1831-1903) French painter was born at St. Thomas in the Danish Antilles of Jewish parents of Spanish extraction. He went to Paris at the age of twenty and as a pupil of Corot came into close touch with the Barbizon masters. Though at first he devoted himself to subjects of the kind associated with the name of Millet his interest was entirely absorbed by the landscape and not by the figures. He fell under the spell of the rising impressionist movement and threw in his lot with Monet and his friends. Like Monet he made sunlight and the effect of sunlight on the objects of nature the chief subjects of his paintings whether in the country or on the Paris boulevards. About 1885 he took up the method of the pointillists but after a few years of these experiments he returned to a broader manner. In the closing years of his life he produced some of his finest paintings in which he set down with admirable truth the peculiar atmosphere and colour and teeming life of the boulevards, streets and bridges of Paris and Rouen. He died in Paris in 1903.

Pissarro is represented in the Caillebotte room at the Luxembourg and in almost every collection of impressionist paintings. A number of his finest works are in the collection of M. Durand Ruel in Paris.

**PISTACHIO NUT**, the fruit of *Pistacia vera* (family Anacardiaceae) a small tree which is a native of Syria and generally cultivated in the Mediterranean region. It has a delicious flavour and is much prized by the Greeks and other Eastern nations. It is not so large as a hazel nut but is rather longer and much thinner and the shell is covered with a somewhat wrinkled skin. The pistachio nut is the species named in Gen. xlii. 11 as forming part of the present which Joseph's brethren took with them from Canaan and in Egypt it is still often placed along with sweet meats and the like in presents of courtesy. The small nut of *Pistacia Lentiscus* not larger than a cherry stone also comes from Smyrna, Constantinople and Greece. *P. Lentiscus* is the mastic tree a native of the Mediterranean region forming a shrub or small tree with evergreen pinnately compound leaves with a winged stalk. Mastic (from *masticare* to chew) is an aromatic resinous exudation obtained by making incisions in the bark. It is chiefly produced in Asia Minor and is used by the Turks as a chewing gum. It is also used as a varnish for pictures. *P. Terebinthus* the Cyprus turpentine tree a native of southern Europe, Asia Minor and North Africa yields Chian turpentine from incisions in the trunk.

**PISTOIA** or **PISTOJA**, a town and episcopal see of Tuscany, Italy, in the province of Florence, from which it is 21 m. N.W. by rail on the main line to Bologna, with a branch to

Lucca. Pop. (19,1) 16,688 (town) 70,397 (commune). It is situated on a slight eminence (10 ft.) near the Ombrone one of the tributaries of the Arno immediately below the Apennines. It is on the site of the Roman *Pistoriae* near which in 6 B.C. Catiline was slain and his forces destroyed. Excavations in the Piazza del Duomo led to the discovery of a large private house (end of 1st century B.C.). During the middle ages Pistoia was the scene of constant conflicts between the Guelphs and Ghibellines here the great struggle took place which resulted in the creation of the Bianchi and Neri factions (Dante *Inferno* xiv. 11). In 130-06 it was besieged and eventually taken by the arms of Florence and Lucca and in 135 it became subject to Castruccio of Lucca. In 1351 it was obliged to surrender to Florence and thenceforth shared its fate.

The city is still surrounded by walls dating from shortly after the siege of 130-06 while two inner lines of streets represent two earlier and inner lines of wall. A number of skilful artists between 137 and 1399 made the great silver altar and frontal of the cathedral now in a chapel on the south side. The cathedral (13th century) has a campanile (218 ft. high) porch and façade with small arcades in black and white marble in the Pisan style as in other churches of Pistoia. It contains many fine sculptures—the monument of Cino da Pistoia lawyer and poet Dante's contemporary (1337) by Cellino di Nese surrounded by his scholars and Verrocchio's monument to Cardinal Forteguerri (1444). The octagonal baptistery is by Cellino (c. 1337). Among the earlier churches the principal is Sant'Andrea (1166) enriched with sculpture in the nave is Giovanni Pisano's magnificent pulpit imitated from his father's pulpit at Pisa. Other churches are S. Giovanni Fuorcivitas (so called because it was outside the line of the earliest pentagonal enceinte of the middle ages) with one of the long sides elaborately adorned with small arcades in the Pisan style in black and white marble also with sculpture by Gruamons (1162) on the façade. Within are a beautiful group of the Visitation by Andrea della Robbia and a fine pulpit by Fra Guglielmo of Pisa (120). S. Bartolomeo in Pantano and S. Pietro Maggiore closely resemble it. San Francesco al Prato is a fine church of the end of the 13th century with interesting frescoes of the school of Giotto. San Domenico a noble church begun in 1294 contains the beautiful tomb of Filippo Lazari by Bernardo and Antonio Rossellino (146-67) and other works of art. The Madonna dell'Umiltà (1494-1567) and S. Maria delle Grazie have fine Renaissance interiors by the local architect Ventura Vitoni. The Palazzo del Comune and the Palazzo Pretorio once the residence of the podestà are both fine specimens of 14th century architecture. The Ospedale del Ceppo has remarkable reliefs in enamelled and coloured terra cotta on its exterior. Besides various medallions there is a frieze of figures in high relief along the whole front—groups representing the Seven Works of Mercy—executed by Andrea della Robbia between 1514 and 1525.

The word pistol is derived (apparently through *pistolese* a dagger—dagger and pistol being both small arms) from Pistoia where that weapon was largely manufactured in the middle ages.

**PISTOIA, SYNOD OF**, a diocesan synod held in 1786 under the presidency of Scipione de Ricci (1741-1810) bishop of Pistoia and the patronage of Leopold grand duke of Tuscany with a view to preparing the ground for a national council and a reform of the Tuscan Church. The synod was attended by 233 beneficed secular and 13 regular priests and decided with practical unanimity on a series of decrees which had it been possible to carry them into effect would have involved a drastic reform of the Church on the lines advocated by Febronius (see **FEBRONIANISM**). The decrees were issued with a pastoral letter of Bishop de Ricci (see **SACRED HEART**), and were warmly approved by the grand duke at whose instance a national synod of the Tuscan bishops met at Florence on the 23rd of April 1787. The temper of this assembly was however wholly different. The bishops refused to allow a voice to any not of their own order and in the end the decrees of Pistoia were supported by a minority of only three. They were finally condemned at Rome by the bull *Auctorem fidei* of the 28th of August 1794.

**BIBLIOGRAPHY**—De Ricci's own memoir *Memorie di Scrittore di Ricci* *co o di l'ro Pistoria* edit d by A onio G lli &c published at Flor nce in 1800. De Ricci's memoirs were published by C sar Cuat at Pi t in 1817. The e were promptly put on the Index Se o D P te *Vi de Scipion de Ricci* (3 vol Bru cl 1825) based on a life and a account of th e od placed on the Inde in 1825. There are war documents n *Lobi Sora c el i T cen* vol ii n n n (Florence 1856). The act of the e od of Pistoria we published in Italian and Latin at Lavia in 1888.

**PISTOL**, a small fire arm designed for quick work and for protection at close quarters and for use in one hand. It was originally made as a single and also double barrelled smooth bore muzzle loader involving no departure in principle from the ordinary fire arms of the day. With the introduction of revolvers and breech loading pistols and the application of rifling to musket barrels came also in the early half of the 19th century the rifling of pistol barrels.

### HISTORY

Pistols are understood to have been made for the first time at Pistoria in Italy whence they receive their name. Camillo Vitelli who flourished in 1540 is the accredited inventor. The first pistols in the 16th century had short single barrel and heavy butts nearly at right angles to the barrel. Shortly afterwards the pattern changed the butts being lengthened out almost in a line with the barrels. These early pistols were usually fitted with the wheel lock (*see Gun*). Short heavy pistol called daggs were in common use about the middle of the 17th century with butts of ivory bone hard wood or metal. A chiselled Italian dagg of 1650 for example had a slightly bell nosed barrel of about 8 in in length and 14 bore. The German wheel lock military pistols used by the Reiters and those made for nobles and gentlemen were prettily and beautifully ornamented. Pistols with metal hafts were common in the 16th and 17th centuries many beautiful specimens of which silver mounted were made in Edinburgh and used by Highlanders. Duelling when in vogue caused the production of specially accurate and well made single barrelled pistols reliable at twenty paces. The pattern of this pistol seldom varied its accuracy at short range equalling that of more modern ones the principle of a heavy bullet and light charge of powder being employed. The first double barrelled pistols were very bulky weapons made with the barrels laid alongside one another necessitating two locks and two hammers. There was also the over and under pistol one barrel being laid over the other. This was a more portable weapon only requiring one lock and hammer the second barrel being turned round by hand after the first had been fired or

FORSYTH LOCK PISTOL AND MODEL PREPARED FOR SUBMISSION TO THE BRITISH HOUSE OF COMMONS IN 1840

as an alternative the flash hole being adjusted to the second barrel by a key. These pistols were first made with flint and steel locks and subsequently for percussion caps. Double over and under pistols were also made with a trigger mechanism that served to discharge both barrels in turn.

**Revolvers.**—A revolver is a single barrelled pistol with a revolving breech containing several chambers for the cartridges thus enabling successive shots to be rapidly fired from the same weapon without reloading. The ordinary pistol has long been superseded by the revolver. The first revolver, fired with the

percussion cap was made with the whole of the barrels six or eight revolving in one piece and was known as the pepper box. It was single action; the hammer was raised and the barrels revolved by the pull of the trigger. The percussion cap was a small cap which could be taken with it owing to the revolving breech and the necessity of the main spring and the consequent trouble which occurred on the trigger. The principle of revolving breech to one barrel which succeeded the pepper box is an old one in the history of firearms dating from the 15th century. In the breech cylinder was revolved by hand in the revolving breech or in the lock a specimen of which is now in the Tower of London but this was subsequently improved by the introduction of a mechanism by which the pull of the trigger or the cocking of the hammer or both do the work. There exists a pistol of the time of Charles I which is rotated into motion by the hammer raised.

In 1814 a self-acting revolver mechanism of a crude pattern was produced in England. Four years later Collier used a separate spring to rotate the chamber. In 1817 an American Samuel Colt produced and patented the first practical revolving pistol the idea of which was obtained by him in 1811 stated from an ancient revolving weapon in the Tower of London. The chambers of the first Colt revolver were loaded with powder and bullets from the muzzle end and each chamber had a nipple that required to be capped. It was the invention of the copper cap that made the Colt revolver possible. Under the old priming system with exposed powder in a pan the difficulty of separate and effective ignition with the revolving cylinder was almost insuperable.

The first American revolver makers caused the cocking of the hammer to revolve the cylinder while the English makers effected this by the pull of the trigger. In 1835 Adams of London and also Tranter of Birmingham brought out the double action revolver in which the revolution of the cylinder could be effected by both these methods. When the revolver is cocked and fired by pressing the trigger greater rapidity of fire is obtained than when the hammer is cocked with the thumb but accuracy is impaired as the trigger requires a long pull and considerable force in order to compress the mainspring and revolve the cylinder. The double action revolver was therefore a great advance on the single action enabling the first and also following shots if desired to be accurately fired by a moderate pressure of the trigger after the hammer had been cocked by the thumb or alternatively the revolver could be rapidly fired if necessary by the trigger action alone. Many revolvers on the Colt principle were in use during the Crimean War and the Indian Mutiny and proved of valuable service to British officers.

As rim fire, pin fire and central fire cartridges were successively introduced breech loading revolvers were constructed to use them. Messrs Smith & Wesson of Springfield USA produced the first metal cartridges for revolvers. Pin fire cartridges paper and metallic were used on the continent of Europe for Lefaucheur and other revolvers and these and rim fire cartridges are still used for revolvers of small calibre. But since the central fire cartridge has proved its superiority for guns its principle has been generally applied to pistol cartridges.

The alteration of the muzzle loading to the breech loading chamber in the revolver involved no decided change of type. The original Colt, as a breech loader remained practically the same weapon as before with a changed chamber. A hinged flap uncovered the breech-chamber on the right and as each chamber reached that point the empty cartridge case was ejected by means of an ejecting rod carried in a tube attached to the under side of the barrel and kept in place by a spiral spring and the chamber reloaded. The next improvement was greater ease and rapidity of extraction obtained first by Thomas's invention of making the barrel and chamber slide forward on the frame of the pistol. The extractor being fast to the pivot retained the cartridges until the chamber was pushed clear of them. Then the chamber was made to swing on one side as in the Colt pistol of that time, enabling all the cartridges to be simultaneously extracted. Finally self-extracting revolvers with jointed frames

were introduced in which the dropping of the barrel forces out the extractor as in an ordinary double gun the extractor acting simultaneously in all the chambers of the pistol. A spring returns the extractor to its place when the empty cartridge cases have been ejected. These are now known as break down actions.

This type of revolver originated with Smith and Wesson but they and other gun makers greatly improved on the original model. Between this American pattern and the English as made by Webley the chief difference is that in the Smith and Wesson model 1888 the holding down bolt or catch was upon the barrel and it engaged with the top of the standing breech whereas in the Webley the bolt was upon the standing breech and gripped the extremity of the hinged barrel. In the 45 1902 model used by the British in the World War this catch was eliminated. The frame was solid and the cylinder made to swing out to the left for the purpose of extracting, ejecting and recharging. The hinged type of revolver is most convenient for use on horseback as the pistol can be opened, the cartridges extracted and the weapon reloaded with one hand.

**Automatic Pistols**—After it had been shown that automatic machine guns could be made which would fire, extract and eject the empty round and also load the next round into the chamber, application of this principle to pistols was attempted and the first automatic pistol to appear was the Borchardt in 1895. This was not very certain in its action and was soon displaced in favour by the Mauser 7.65mm 1898 model. This latter was provided with a wooden holster which could be attached to form a stock or butt. Later the bore was increased to 9mm and in this pistol a more powerful cartridge was used giving to its nickel jacketed bullet a high velocity. This latter weapon provided with a holster and sighted up to 1000 yards was used occasionally by the Boers during the last Boer War. Thus it may be said the vogue was started and great development on these lines took place both in Europe and America. (X)

#### MODERN REVOLVERS

Modern automatic pistols have many advantages over contemporary revolvers and the armies of most nations are now armed with them with the exception of Britain, France and at one time Russia. In the British navy the 4.5 Webley Revolver is used.

All revolvers are hand operated but modern automatic pistols all rely for their operation on the effect of firing a round. The automatics are claimed to have the following advantages over revolvers—(a) Rapidity of fire (b) rapidity of recharging (this is done by filled magazines) (c) each magazine holds more rounds (d) flatter and more easily carried and other minor points. Automatic implies continuous action in a machine gun but it has not that meaning when applied to pistols which though called automatic are really semi-automatic in action and require a separate pull of the trigger to fire each shot.

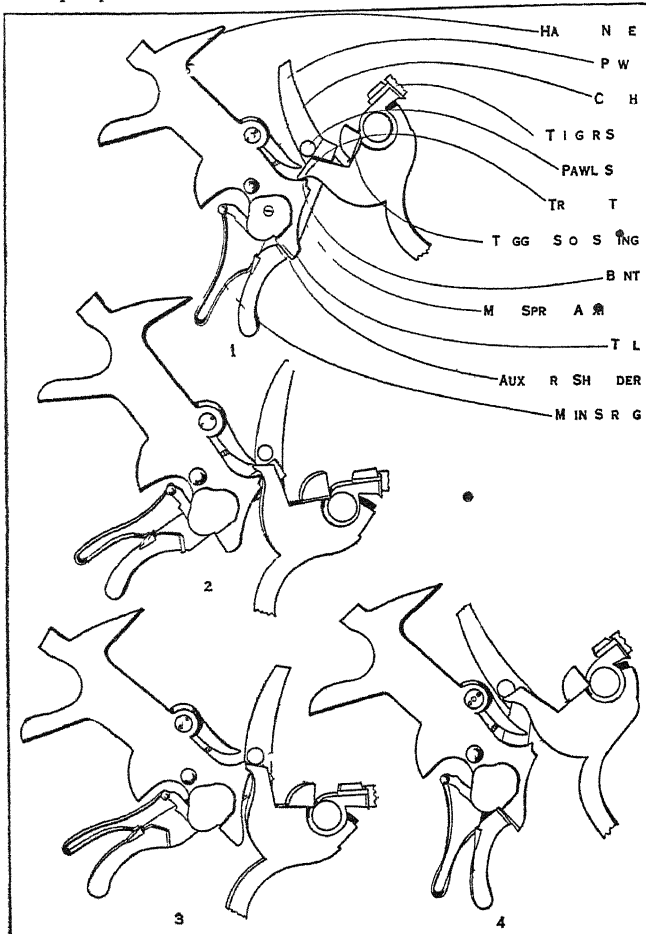

While admitting the advantages claimed for automatics it is held that the revolver is—(1) More certain because (a) it is positively manipulated by hand (b) it is immune from questions of incorrect functioning due to variable recoil with slightly erratic ammunition (c) being less complicated it is more free from troubles due to mud and dirt or lack of lubrication (2) A miss fire is instantly corrected by pulling the trigger without moving the revolver or altering the aim. With the Automatic the weapon has to be lowered, eyes removed from the enemy or target and both hands used to overcome the stoppage that arises from the miss fire, a difference perhaps of a few seconds of time that may be of vital importance (3) Less liable to accidental discharge.

In ammunition used for automatic pistols the bullets have cupro-nickel envelopes and they usually have a velocity rather more than medium. These envelopes help to facilitate the feeding of the round without friction or jamming in the magazine and also when being forced from the magazine into the chamber. Were these bullets of unjacketed lead they might not take the rifling in the barrel at the velocities employed and hence the shooting would be inaccurate. Such jacketed bullets being much harder than lead have more penetrating power and a great deal of their energy may be wasted and expended in the further forward motion of the bullet

after penetration.

The different makes of the modern revolver may be said to differ from each other in details only and a description of the four main features of the revolver mechanism will be generally applicable to all. The four main features are cocking and firing, cylinder rotation, rebound and safety.

**Cocking and Firing**—All revolvers now are of the double action type previously described i.e. cocking the hammer with the

WEBLEY REVOLVER (1) NORMAL FIRING POSITION (2) SECOND FIRING POSITION SHOWING TRIGGER MECHANISM (3) THIRD FIRING POSITION (4) FOURTH FIRING POSITION

thumb or pulling through with the trigger when the hammer is forward. In both cases the hammer rotates about its axis and in so doing compresses a spring, the mainspring, which is the driving force of the hammer (see diagram).

As the hammer is caused to rotate by the thumb in single action its toe bears against and underneath the tail of the trigger and this is caused to revolve about its axis until a point is reached when a bent in the toe of the hammer engages with the tail of the trigger. The mainspring having been compressed keeps the trigger in engagement with the bent of the hammer. If the trigger now be pulled it will rotate still further until the tail of the trigger slips from the bent of the hammer when the hammer will fly forward to fire the round. In the pull through action an accessory to the hammer comes into play, namely the hammer catch. This at its top end rotates round an axis on the front of the hammer while its bottom end is caused to protrude by a spring housed between the two and known as the hammer catch spring. When the trigger is pulled its tail rotating upwards engages with the bottom of the hammer catch and so rotates it and the hammer in the opposite direction. Eventually a point is reached when the hammer catch and the trigger tail clearing each other the hammer flies forward and fires the round.

**Cylinder Rotation**—Another feature common to all revolvers is the means of rotating and positioning the cylinder of chambers. Around the central axis of the cylinder and protruding from its

rear face are the teeth of the ratchet one tooth per chamber. To the inside of the tail of the trigger is pivoted the pawl. When the trigger is pulled the tail rises bringing with it also the pawl. The top of the pawl bears against a tooth of the ratchet so when the pawl rises it rotates the ratchet and brings up the next chamber the full distance to place it in true alignment with the barrel (see diagram).

To prevent over rotation of the cylinder stops are provided which prevent movement beyond the exact amount required to ensure this alignment. Thus while these stops prevent over rotation and the pawl prevents rebound perfect alignment of the chamber and barrel is secured as is also that of the cartridge cap and hammer. These cylinder stops pivoted to the trigger and influenced by a spring protrude upwards through the bottom of the frame and engage in slots on the outside circumference of the cylinder. They are so constructed as to disengage from the slots as the pressure on the trigger is released and the latter starts to go forward. Were these stops to remain in their slot the cylinder could not be rotated. (The Webley 455 Revolver has two such stops others usually have one.)

**Rebound Action**—Furthermore the cylinder could not be rotated were the hammer nose to remain in the indentation made in the cap of the cartridge case after being struck by the hammer. To meet this rebound action is employed i.e. as the trigger starts to move forward after a shot has been fired the hammer is caused to revolve slightly to the rear and thus clear its nose from the cartridge cap (see diagram).

In the Webley and Colt this action is effected by the lower arm of the mainspring pressing down on the mainspring auxiliary a shoulder on which bears against the tail of the hammer so rotating it and returning it to its normal position.

**Safety Action**—Accidental discharge through the hammer being knocked forward is also guarded against. In the Webley and Colt the tail of the hammer is shaped so that if its top be pushed forward its tail causes the auxiliary to rise. The front end of this bears against a stud on the pawl so raising it. It in turn raises the trigger which meets the down coming hammer catch thus preventing further hammer movement (see diagram).

These last two actions are provided for in the Smith & Wesson by a block underneath the hammer. When the trigger is pulled this block is forced to the rear against a spring. As the trigger is released the block moves forward a step on it meeting a step on the tail of the hammer thus effecting the rebound action. As the trigger moves further forward the block passes under the hammer tail and so prevents any forward movement by the top of the hammer.

The French army revolver is the 8mm Modele d'Ordonnance. It is of the solid non break down type and the cylinder swings

THE LOCK OF A COLT AUTOMATIC PISTOL

out to the right for ejection and loading. In the 3 Russian Nagant endeavours are made both in the action and the ammunition to bridge the space between the front of the cylinder and the breech of the barrel through which gas escapes a defect which is present in all other revolvers.

### AUTOMATIC PISTOLS

Such weapons are now numerous and vary greatly in design with calibres ranging from .455 to .250 inches. In all cases

however their operation is dependent on the result of firing a round. If the bullet of the cartridge be not supported in the chamber when it is exploded it will be blown to the rear the gas will cause the bullet will not be projected and the firer will be probably killed.

Automatic pistols are divided into two main types i.e. (a) those in which the barrel and bolt are positively locked together

THE LOCK OF A WEBLEY & SCOTT AUTOMATIC PISTOL

gather till the bullet exits. (b) Those dependent on inertia with no mechanical locking. The latter for sealing the breech rely on the weight of the moving parts which place the round in the chamber and which hold it there by the assistance of strong springs together with the friction on extraction caused by the cartridge case expanding under the explosion and gripping the walls of the chamber.

The small bore pocket pistols are frequently of type (b). However in view of the requirements of a revolver or pistol previously referred to type (a) which permit of a heavy bullet and a heavy charge are usually the most employed for military purposes. There are two sub divisions of type (a) namely (1) Those in which the barrel and bolt recoil together in the same plane for a short distance prior to unlocking (Luger Parabellum, Mauser [Germany], Frommer) (2) A lowering movement of the barrel during recoil which unlocks itself from the bolt after a short distance (Webley & Scott, Colt).

The Luger functions on somewhat similar lines to the Maxim or Vickers Machine Gun. In it the bolt is supported by a toggle joint the centre hinge of which is below the level of the ones on either side of it and bears against the metal of the frame. Locked in this way barrel and bolt recoil together until the centre hinge meets a ramp and is forced upwards so breaking the joint and knocking the bolt back against the compression of a spring.

Not quite similar to (1) and (2) above is a third form of barrel movement i.e. a turning motion of the barrel during recoil thus bringing about unlocking (Steyr and Savage).

Of type (b) a Browning 9mm Military Model manufactured in Belgium and marked FN (Fabrique Nationale) is the weapon of Belgium, Holland and of some S. American States.

Owing to the similarity in outward appearance between various automatic pistols not much can be learnt from photographs. However on this page are diagrammatical sketches of the principles employed in some of the locking actions mentioned above.

**Magazines**—All these pistols have magazines holding from 7-10 rounds in three of which the magazines can be loaded while assembled by means of chargers namely the Bayard (out of date) Mauser and the Steyr. Safety catches are usually of two types namely thumb levers and grip levers. The former when applied disconnect the hammer from the sear so that pulling the trigger has no effect. The grip levers are at the back of the stock and when not gripped by the hand as when firing cause the hammer and sear to be disconnected with the same result as above.

Holding open devices are embodied in most automatic pistols and warn the user that the magazine is empty. The magazine platforms or levers operated by them rise when the magazine is empty.

<sup>1</sup>The cartridge cases of automatic pistols are always cylindrical. The greatest friction and therefore gripping of the chamber is produced by such cases when expanded.

<sup>2</sup>In this type the barrel and sleeve lock the bolt which is solid with the sleeve seals the breech when this locking is effected.

zine is empty and hold back the recoiling parts thus putting the pistol temporarily out of action

A danger common to most automatic pistols is that when the magazine is removed a live round is usually left in the chamber and if forgotten may result in an accident Hammerless pistols give no indication as to whether the pistol is cocked or not On the other hand with hammers projecting at the rear of the pistol there is a possibility of cocking the hammer by an accidental knock or by friction

There is only one well known sample of a semi automatic revolver namely the Webley Fosbery 45 In it is the usual six chambered cylinder When the round is fired the cylinder and barrel recoil and in so doing the cylinder is made to turn half the distance necessary for aligning of the next chamber with the hammer After recoil a strong spring forces the recoiling portions forward and the cylinder rotates through the remaining necessary distance (H R A)

**PISTOLE** The French name given to a Spanish gold coin in use from 1551 it was a double *escudo* the gold unit and was worth 16s 11½d sterling The name was also given to the *louis d'or* of Louis XIII of France and to other European gold coins of about the value of the Spanish coin

**PISTON** see STEAM ENGINE INTERNAL COMBUSTION ENGINES PUMP

**PITCAIRN**, a borough of Allegheny county Pennsylvania USA 15 m SE of Pittsburgh on the Pennsylvania railroad Pop (1900) 5758 (95% native white) 1950 Federal census 6317 The Pennsylvania company has railroad shops and freight yards here employing large numbers Electrical goods bricks and concrete blocks are manufactured in the borough and there are coal mines in the vicinity The borough was incorporated in 1894

**PITCAIRNE, ARCHIBALD** (1652-1713) Scottish physician was born at Edinburgh on Dec 25 1652 He took his MA degree at Edinburgh university in 1668 and after courses in Edinburgh and Paris he obtained in 1680 the degree of MD at Rheims He began practice at Edinburgh and in 1691 was appointed professor of medicine at Leyden Among his pupils were Richard Mead and H Boerhaave and both of them attributed much of their skill to what they learned from Pitcairne In 1693 Pitcairne settled once more in Edinburgh He persuaded the Edinburgh town council to permit himself and certain of his medical friends to treat without fee the sick paupers in Paul's Work on condition of being allowed to dissect such of the bodies as were unclaimed by their relatives In this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine He died on Oct 20 1713

**PITCH** The name of various substances of dark colour and of extremely viscid and tenacious consistency when subjected to heat (O Eng *pic* an adaptation of Lat *pix picis* Gr *πισσα πιττα* allied with Gr *πιτυς* pine tree Lat *pinus*) Strictly the term is applied to the resinous substance obtained as a solid residuum by the distillation of wood tar (see TAR) or the non resinous substance similarly produced from coal tar (*qv*) The name is also applied to the natural mineral substances *ie* as phalt or bitumen (*qqv*)

**PITCH, MUSICAL** The pitch of a musical sound is precisely defined by a vibration number recording the frequency of the pulsations of a tense string a column of air or other vibrator in a second of time In Great Britain and America the complete vibration to and fro is taken as the unit elsewhere the vibration in one direction only The only official standard is the French dating from 1859 preserved by a tuning fork vibrating 870.9 (double vib 435.45) at a temperature of 15 Centigrade (59 Fahr) in a second The vibration number stated in the edict establishing in the year named the diapason normal is 870 (435) Vibrations increase in rapidity as a note rises and decrease as it falls Any note may be a pitch note For orchestras custom has settled upon *a* in the treble clef for organs and pianos in Great Britain *c'* and for modern brass instruments *b* flat

We are not without a clue to the pitch usual in the classic Greek and Alexandrian ages the vocal octave to which the lyre was adapted was noted as from *e* to *e'*. As in choruses barytone

and low tenor singers always prevail *d-d'* at French or at medium pitch would really be the Greek singing octave we may therefore regard it as a tone lower than that to which we are accustomed But to sing the lower Greek modes in or near the vocal octave it was necessary to transpose (*μεταβολη*) a fourth upwards which is effected in modern notation by a flat placed upon the B line of the staff thus modulating from our major key of C to that of F This transposition has had as we shall see much to do with the history of our subject ultimately influencing the ecclesiastical chant and lasting until the 17th century of our era It does not appear from any evidence that the keyboards—when there were more than one—of the early organs were arranged for transposition but it is certain that the Flemish harpsichords to 1650 were made with double keyboards to accommodate it (see Hipkins's *History of the Pianoforte* 1897) But a positive identity of pitch cannot be claimed for any period of time and certainly not for the early organs the foot rule of the organ builder which had to do with the lengths of the pipes and which varied in every country and province could easily cause a difference of a semitone Scale and wind pressure are also important factors But with all these often opposed conditions we find less variation than might be expected the main and really important divergence being due to the necessity of transposition which added a very high pitch to the primarily convenient low one

The first to attempt to define pitch would seem to have been Arnold Schlick (*Musica ausgeteutsch und ausgeogen* Heidelberg 1511) who gives a measure a line of 4½ Rhinish inches which he says multiplied sixteen times should be the lowest F of a small organ He gives no diameter or wind pressure Dr A J Ellis used this indication to have an organ pipe made which with one sixteenth diameter and a wind pressure of 3½ in at one fourth Schlick's length gave *f* 301.6 from which he derived a just major third of *a* 377 which would compare very well with an old Greek *a* Schlick goes on to say the organ is to be suited to the choir and properly tuned for singing that the singer may not be forced to sing too high or too low and the organist have to play chromatics which is not handy for every one Further he says pitch cannot be exactly defined because voices vary he nevertheless gives the measure above mentioned for the low *f* but if a larger organ is built to include the still lower C then this C must be of the same measurement the reason being that a greater part of church music ends in *grambus* a word understood by Schlick's editor to mean the transposition of a fourth The larger high pitch organ will therefore be at *a* 50.6

The Halberstadt organ was according to Praetorius built in 1361 and repaired or rebuilt 1495 He gives the longest pipe of this organ B natural as 31 Brunswick feet and the circumference 3½ ft He further tells us this pitch was a tone nearly a tone and a half higher than a suitable church pitch (*Chorton*) for which he gives a diagram Dr Ellis had pipes (now preserved in the Royal Institution London) made to reproduce both these pitches at 3½ in wind pressure The Halberstadt pitch was found to be *a* 505.8 the *Chorton* 424.2 Ellis used mean tone temperament in calculating this lower pitch but as he used just intonation for the Halberstadt it seems preferable to substitute it for the *Chorton* thus reducing it to *a'* 422.8 Praetorius's *Cammerton* or chamber pitch formulated in his diagrams for voices and instruments is he says a whole tone higher equivalent therefore to *a* 475.65 Nearly all the German organs were tuned to this higher pitch The lower vibration number is justified by the three divisions of the male voice bass tenor and alto as given by Praetorius whose *Cammerton* very closely corresponds with Bernhardt Schmidt's Durham organ 1663-1668 the original pitch of which has been proved to have been *a* 474.1 The Halberstadt pitch is nearly a semitone higher which again agrees with the statement of Praetorius and also Schlick's high C organ Yet it would seem that there had been a still higher pitch used in the old ecclesiastical music In one passage Praetorius distinctly says the old organ high pitch had been a whole tone above his *Cammerton* with which we shall find his *tertia minore* combines to make the required interval The term *tertia minore* or *inferiore* is used by Praetorius to describe

a low pitch often preferred in England and the Netherlands in Italy and in some part of Germany. An organist in the case of transposing a whole tone down from the *Camerton* would for the *tertia minore* have to transpose a minor third.

Corroboration of this pitch is found in Silbermann's organ in Strasbourg minister (1715-1716) the pitch of which taken in 1700 and reduced to 59° Fahr. as are all pitches in his article (1709). An old organ at Versailles (1789) was very near this example *a* 395. Ellis gave Dom Bedos (*L'Art du facteur d'orgue* Paris 1766) as authority for a mean tone *a* 366. Sir F. G. Ouseley's comparison of the church and chamber pitches of Oratorio Gibbons (*see* Ellis's lecture) clearly shows the minor third in Great Britain in the first half of the 17th century. But the narrowness continued. Bernhardt Schmidt better known in England as Father Smith was invited about 1660 to build the organ for the Chapel Royal Whitehall. Two years later he built the organ in Durham Cathedral *a* 441 difference a whole tone and practically agreeing with the *Camerton* of Praetorius. The Hampton Court organ of 1690 shows that Schmidt had further lowered his pitch a semitone to *a* 441.7. What happened at Durham was that at some subsequent date the pipes were shifted up a semitone to bring the organ into conformity with this lower pitch with which it is probable Schmidt's organs in St. Paul's and the Temple and also Trinity College Cambridge agreed.

The final adoption of the low church pitch as in the 15th century was no doubt influenced by the introduction of the violin which would not bear the high tension to which the lute and viols had been strained. Harpsichords had long been preferred to the *tertia minore*. The Chorton of Praetorius *a* 428 is practically the same pitch as that of the fork the possession of which has been attributed to Handel *a* 445. It is a very fair mean between G Silbermann's 18th century Dresden pitch *a* 415 and the organs of Renatus Harris *a* 487. Stein tuned Mozart's piano to a fork *a* 416 and the Broadwood pianos used at the first London Philharmonic Society concerts (1813) were tuned to a fork *a* 506.8 which gives a mean tone *a* 443.

According to Schindler (*Nieder-rheinische Musik Zeitung* 1855 Nos. 8 and 9) and the report of the French Commission 1859 the rise in pitch began at the Congress of Vienna in 1816 the military bands being the cause. With the improvements in wind instruments this continued as more brilliant effects were gained. In 1823 Weber's *Euryanthe* is recorded as having been played in Vienna at *a* 451.5 and in 1834 Kreutzer's *Nachtlager* at *a* 440. The measurements are doubtful but the upward tendency is clear. Scheibler by his simple and accurate tonometer has recorded pitches in Vienna about 1834 from *a* 433.9 to 440. About that time or it may be a few years earlier Sir George Smart established a fork for the Philharmonic Society *a* 435.2. Forks intended for this vibration number stamped Philharmonic were sold as late as 1846. But about that year the performing pitch of the Society had reached 452.5. Sir Michael Costa was the conductor 1846-54 and from his acceptance of that high pitch the fork became known as Costa's and its inception was attributed to him though on insufficient grounds. In 1874 a further rise in the fork to *a* 454 was instigated by Sir Charles Halle. The British army is required by His Majesty's Rules and Regulations to play at the Philharmonic pitch but a fork tuned to *a* 452.5 in 1890 was the standard for the Military Training School at Kneller Hall until after an Army Order of Dec. 1928 the military bands followed the Philharmonic Society's adoption in 1896 of the diapason normal.

It was the irrepressible upward tendency that caused the French Government in 1859 acting with the advice of Halevy Meyerbeer Auber Ambroise Thomas and Rossini to establish by law the diapason normal *ie* *a* 439 at 68° Fahr. or *a* 435 at 59° Fahr. Other countries have gradually followed and with few exceptions the low pitch derived from the diapason normal may be said to prevail throughout the musical world. Great Britain was the last to fall in but the predominance of the low pitch is assured. The proprietors of Queen's Hall London did much for it when they undertook the alteration at great expense, of their large concert organ which had only just been erected. In 1896 the Philharmonic Society adopted the diapason normal and in 1899

Mr. Broadwood made a successful effort to get the same vibration number accepted by their competitors in Great Britain. The high pitch remains only where there are large concert organs, no *vi* lowered and with the military and brass band.

The consideration of temperature affecting the use of a standard pitch was not attended to when the French Government issued its *ordonnance*. The *ie* *C* attached to the description of the standard pitch is intended for the definition and verification of the fork only. The alteration of the fork due to the temperature of the air is not considered but wind instruments and particularly the organ rise almost proportionately to the increase in temperature of the surrounding air because sound travels at an enhanced rate as the temperature rises. The coefficient of this rise is equivalent to half a vibration (0.5) per degree Fahr. per second. The French Commission in establishing the diapason normal should have chosen a temperature of 0° C. There would then have been less disturbance owing to the breath of the players and heat of the theatres or concert rooms. As things are even the established diapason normal implies a variation from 4 to 440 vibrations a second for *a* inasmuch as temperature must always be reckoned with.

In writings on music the pitch of a note is indicated in various ways when it is desired to convey this without the employment of actual notation. Thus organists peak or great *C* double *C* and tenor *C* to indicate the notes sounded by pipes of 16ft. 8ft. and 4ft. respectively the same notes being also indicated alternatively by the lettering CCC CC and C. Another system is based on the employment of different types (*ie* either capitals or small italic letter) supplemented by small strokes placed above or below the letters as the case may be. Thus under this system 16ft. *C* is represented by *C* 8ft. *C* by *C* without any stroke 4ft. *C* by *c* the *C* above (middle *C* on the pianoforte) by *c* the *C* above that (or treble *C*) by *c'* the *C* above that again by *c''* and so on the intermediate notes in each octave being of course similarly indicated. Or instead of strokes small numerals are sometimes used *eg* *C* *C*<sub>1</sub> *c*<sub>1</sub> *c*<sub>2</sub> etc. The expressions in alt. and in altissimo are also employed for the same purpose in alt. signifying the notes in the octave beginning with the *C* above the treble octave (*g*) and in altissimo those in the octave above (*g* *a* *b* etc.) (*See* ALT.) (A. J. H. V.)

**PITCHBLENDE or URANINITE**, a mineral species consisting essentially of uranium oxide of importance as a source of uranium and radium. It is a very heavy (specific gravity 9.0-9.7) compact mineral with a conchoidal to uneven fracture and a brownish to velvet black colour and pitchy lustre. Crystals are rare they have the form of regular octahedra or less often of cubes. The hardness is 5½ and the streak is brown with a greenish tinge. The mineral has been known since 1727 to occur at Jachymov (Joachimsthal) in Bohemia and it was early called pitchblende because of its appearance but its true nature was not recognized until 1789 when M. H. Klaproth's analysis of it resulted in the discovery of the element uranium. Analyses of material from different localities exhibit wide variations in chemical composition in addition to uranium oxides there are thorium cerium (and lanthanum) yttrium and lead oxides each varying in amount from a trace up to 10%. Calcium iron magnesium manganese silica water etc. are also present in small amounts and the content of uranous and uranic oxides (UO<sub>2</sub> 21-72 UO<sub>3</sub> 13-59%) also vary considerably. The mineral is often described as a uranate of uranyl lead thorium and cerium but in the least altered material from Branchville in Connecticut the uranous oxide predominates whilst in altered specimens uranic oxide is in excess. In the closely allied mineral, thoranite thorium predominates (ThO<sub>2</sub> 76 UO<sub>2</sub> 12%). Since the dioxides of uranium thorium and cerium may be obtained artificially as cubic crystals it seems probable that pitchblende consists of isomorphous mixtures of these dioxides the uranic oxide being due to oxidation.

The radio-active properties of pitchblende are of special interest. The fact that this mineral is more strongly radio active than metallic uranium led to the discovery in it of the elements radium polonium and actinium. When pitchblende is ignited

or dissolved in dilute sulphuric acid a gas is evolved which consists largely of helium and argon terrestrial helium was first recognized in this mineral

Pitchblende occurs either as a primary constituent of granitic rocks or as one of secondary origin in metalliferous veins. Octahedral crystals (cleveite and broggerite) occur in the pegmatite veins of southern Norway being occasionally found in the felspar quarries at Moss Arendal and other places. Crystals are found under similar conditions at Middletown and Branchville in Connecticut Llano county in Texas (nivenite) Mitchell county in North Carolina Villeneuve in Quebec and other American localities. Thorianite found as water worn cubes in the gem gravels near Balanoda in Sabaragamuwa province Ceylon has also no doubt been derived from crystalline rocks. On the other hand the mineral found in metalliferous veins and to which the name pitchblende is more properly restricted never occurs as crystals but as compact masses rendered more or less impure by admixture of other minerals the specific gravity being sometimes as low as 6.5 thorium cerium etc are absent and radium and helium are present in smaller amounts. This variety occurs with ores of silver lead copper nickel cobalt bismuth etc at Johanngeorgenstadt Marienberg and Schneeberg in Saxony Jachymov and Příbram in Bohemia Gilpin county in Colorado St Just Redruth Grampound Road and elsewhere in Cornwall and at Kasola in Katanga Belgian Congo.

Often associated with pitchblende and resulting from its alteration is an orange yellow amorphous gum like mineral called gummite which is a hydrous uranic oxide with small amounts of lead calcium iron etc.

**PITCHER PLANTS**, in botany the name given to plants in which the leaves bear pitcher like structures or are pitcher like in form. The plant generally understood by this name is *Nepenthes* family Nepenthaceae a genus containing nearly 60 species natives of tropical Asia north Australia and (one only) of Madagascar North Borneo is especially rich in species. They are shrubby plants climbing over surrounding vegetation by means of tendril like prolongations of the midrib of the leaf beyond the leaf tip.

The pitcher is a development at the end of the tendril and is generally tubular in form and often shows a pair of wings running longitudinally on the outer surface. The mouth of the pitcher has a corrugated rim (peristome) formed by incurving of the margin the convex surface of which is firm and shining. It is traversed by more or less prominent parallel ridges which are usually prolonged as teeth beyond the infolded margin. Above the mouth is the lid (operculum) which varies in size from a small narrow process to a large heart shaped expansion. A study of the development of the pitcher especially in the young pitchers of seedling plants shows that the inflated portion is a development of the midrib of the leaf while the wings which are especially well represented in the terrestrial type of pitcher represent the upper portion of the leaf blade which has become separated from the lower portion by the tendril the lid is regarded as representing two leaflets which have become fused. The short straight or curved process from the back of the pitcher behind the lid repre-

sents the organic apex of the leaf.

The size of the pitcher varies widely in the different species from a thimble to the size of a quart pot. The colour also varies considerably even in different pitchers of the same individual according to age light exposure or soil conditions. Insects are attracted to the mouth of the pitcher by a series of glands yielding a sweet secretion which occurs on the stem and also on the leaf from the base of the leaf stalk to the lid and peristome.

SIDE SADDLE FLOWER (*SARRACENIA PURPUREA*) SHOWING LEAVES THE WHOLE OF WHICH FORM THE PITCHERS AND A B AND C SHOWING THE MINUTE STRUCTURE OF PITCHERS (A AND C FROM *S. FLAVA*)

Embedded in the incurved margin of the rim which affords a very insecure foothold to insects are a number of large glands secreting a sweet juice. The cavity of the pitcher is in some species lined throughout with a smooth glistening surface over which glands are uniformly distributed. These glands secrete a watery fluid which is found in the pitcher even in the young state while it is still hermetically closed by the lid. In other species the glands are confined to the lower portion of the cavity surface while the upper part bears a smooth waxy surface on which it is impossible for insects to secure a foothold. This area is termed the conducting area as distinguished from the lower or detentive gland bearing area. Insects especially running insects which have followed the track of honey glands upwards from the stem along the leaf reach the mouth of the pitcher and in their efforts to sip from the attractive marginal glands fall over into the liquid. The smooth walls above the liquid afford no foothold owing to the presence of minute waxy scales and they are drowned. The fluid as first secreted is not acid and contains no digestive enzyme but the presence of an insect causes the glands to secrete both acid and a proteolytic (protein dissolving) enzyme. The bodies of the insects are thus digested and the products of digestion absorbed by the glands in the pitcher wall. Thus *Nepenthes* secures a supply of nitrogenous food from the animal world in a manner somewhat similar to that adopted by the British sundew butterwort and

PITCHER PLANT (*CEPHALOTUS FOLLICULARIS*) SHOWING LEAVES PITCHERS AND TALL FLOWER STEM WITH SMALL FLOWERS

other insectivorous plants. In spite of the presence of a digestive enzyme the pitchers constantly contain an association of living organisms including diatoms, *Acarna* larvae of Diptera etc.

The side saddle plant *Sarracenia* native of the eastern United States is also known as a pitcher plant. There are about 10 species of herbs with clusters of radical leaves some of which are more or less trumpet or pitcher shaped. The last leaf is broadly feathery but is succeeded by a short leaf which is the pitcher which represents a much enlarged nectarial with a waxy like lamina. Above the rim of the pitcher is a broadened lid which is also a laminar development. The urticar of the leaf especially the laminar wing bears glands which in spring exude large quantities of nectar. The lid and mouth of the pitcher are brighter coloured than the rest of the leaf which varies from yellow green to deep crimson in different species and in individuals according to exposure to sunlight and other conditions. This forms the attractive area and the inner surface of the lid also bears a large number of glands as well as downward pointing hairs each one having a delicately striated surface.

Below the lid is the conducting surface of glaucous epidermal cells with short downward directed points which facilitate the descent but impede the ascent of an insect. Then comes the glandular surface

upon the pitcher it is that some drop their eggs into the putrescent mass where their larvae find abundant nourishment while birds often sit upon the pitchers with their beak and devour the maggots of their turn.

*Cephaelis* is a native of south-west Australia a small herbaceous plant whose ordinary habit is to the ground as a pitcher. The pitcher is usually a small one in general form.

the of *Nepenthes*. The lid is especially attractive to insects from its bright colour and honey secretion. Three wings lead up to the mouth of the pitcher on the inside of which a row of sharp spines points downward and below this a circular ridge armed with papillae serves as a conducting area. A number of glands on the interior of the pitcher secrete a fluid in which insects are found but how they are utilized is still obscure.

**PITCHSTONE**, in petrology, a glassy igneous rock having a resinous lustre and breaking with a hollow or conchoidal fracture (Ger. *Pechstein* from its resemblance to pitch). It differs from obsidian principally in its rather dull lustre for obsidian is bright and vitreous in appearance. Pitchstones also contain water in combination amounting to from 5 to 10% of their weight or 10 to 20% of their volume. The majority of the rocks of this class occur as intrusive dikes or veins; they are glassy forms of quartz porphyry and other dike rocks. Their dull lustre may be connected with the great abundance of minute crystallites and microclites they nearly always contain; these are visible only in microscopic sections and their varied shapes make pitchstones very interesting to the microscopist.

Although pitchstones of Devonian age are known (e.g. the glassy dacite of the Tay Bridge in Scotland and the andesite pitchstones of the Cheviots) most of them are Tertiary or recent as like all natural glasses they tend to crystallize or become devitrified in course of time. In some of the older pitchstones the greater part of the mass is changed to a dull felsitic substance while only nodules or kernels of unaltered glass remain. Some are very acid containing 70 to 75% of silica and have close chemical affinities to granites and rhyolites; others contain more alkalis and less silica being apparently vitreous types of trachyte or keratophyre; others have the composition of dacite and andesite but the black basaltic glasses are not usually classified among the pitchstones. Very well known rocks of this group occur at Chemnitz and Meissen in Saxony. These rocks are brown or dark green in colour very frequently perlitic and show progressive devitrification starting from cracks and joints and spreading inwards through the mass. For a long time the pitchstone dikes of Arran, Scotland have been famous for the great beauty and variety of skeletal

PITCHER PLANT (NEPENTHES GRACILIS) SHOWING GENERAL HABIT OF GROWTH AND A B AND C MINUTE STRUCTURE OF PITCHER PLANT

face which is formed of smooth polished epidermis with numerous glands that secrete the fluid contents of the pitcher and finally the detentive surface of which the cells are produced into long and strong bristles which point downwards and meet in the centre of the diminishing cavity so as to render escape impossible. The secretion wets an insect very rapidly but its digestive power is uncertain. The pitchers accumulate vast quantities of insects in the course of a season and must thus abundantly manure the surrounding soil when they die. Moreover the feast is largely shared by unbidden guests. Not to speak of insects which feed

ton crystals they contain they are dull green in hand specimens some of them contain phenocrysts or felspar augite etc others do not but in all there is great abundance of branching feathery crystalline growths in the ground mass minute crystalline rods being built together in aggregates which often recall fro t pattern It is supposed that they consist of hornblende In addition to these larger growths there are many small microclites scattered through the glass also hair like trichites and fine rounded globulites When phenocrysts are present the small crystals are parted on their surfaces like grass on a turf covered wall The pitchstones are believed to proceed from the great eruptive centre of early Tertiary times in western Scotland Another pitchstone of the same period forms a great craggy ridge or cum in the island of Eigg (Scotland)

In chemical composition this latter rock resembles the trachytes rather than the rhyolites in Eigg and Skye there are many dikes of pitchstone mostly of intermediate rather than of acid character all connected with the great eruptive activity which characterized that region in early Tertiary times

The following analyses give the chemical composition of a few well known pitchstones —

	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	FeO	MgO	CaO	Na <sub>2</sub> O	K <sub>2</sub> O	H <sub>2</sub> O
I Meissen Saxony	74	11.6	0.5	0.5	1.35	2.86	3.80	7.64
II Corrieigills Arran	70	11.6	5.4	tr	1.55	0.61	5.01	5.45
III Scur of Eigg Scotland	65.1	14.01	4.43	0.9	2.01	4.15	6.08	7.0

The first two of these contain much water for rocks the ingredients of which are but little decomposed They are of acid or rhyolitic character while the third is richer in alkalis and contains less silica it belongs more naturally to the intermediate rocks (or trachytes)

**PITE, WILLIAM ALFRED** (1860—) **FRIBA** British architect was born on Aug 4 1860 in London He studied at the National Art Training School afterward winning several studentships Later he became vice president of the Architectural Association and examiner and member of council of the RIBA His works include an important series of hospitals in London and the provinces including King's College Hospital three churches of which the Perceval Memorial church at Ealing is perhaps the most interesting and a number of private houses

**PITESTI** The capital of the department of Arges Rumania beautifully situated among the outlying hills of the Carpathians on the river Arges which is here joined by several smaller streams and on the junction of the main Bucharest Craiova line with branches to Campulung and Curtea de Arges Pop (1930) 19,650 The surrounding uplands produce good wine fruit and grain and are rich in petroleum and salt the town is a centre of the petroleum industry It has lacquer and varnish mills and distilleries

**PITHECANTHROPUS**, the name given by Dr Eugene Dubois of the Dutch army medical service to the creature (*P. erectus*) of which he found fossilized remains in Java These fragments consisted of a thigh bone two teeth and the upper part of a skull and were unearthed in 1891-92 on the left bank of the Bengawan river near Trinil The skull appears to have been low and depressed with strong supraciliary ridges the teeth are very large and the femur is quite human The teeth and skull were found together the femur a few yards away a year afterwards The discoverer however stated it as his belief that the fragments were portions of the same skeleton and belonged to a creature half way between man and the higher apes and of the Pleistocene age and in spite of opposition this is now admitted

See Dubois *Pithecanthropus erectus* (1894) a later paper read by Dr Dubois before the Berlin Anthropological Society translated in 1898 *Smithsonian Report* Sir A. Keith *Antiquity of Man* (1915)

**PITHIVIERS**, a town of north central France in the department of Loiret 28 m NNE of Orleans on the railway to Malesherbes Pop (1931) 5,601 The town is an important centre for the saffron of the region of Gâtinais The shrines of St Solomon (9th century) and of St Gregory, an Armenian

bishop (10th century) formed the nuclei of the town and the donjon built in the 16th century for H. Louis lady of Pithiviers was one of the fine old buildings

**PITHOM**, one of the ancient cities stated to have been built for the Hebrews in Goshen during the Oppression (Exodus 1) It lay here the Hebrew form of the Egyptian Pithom House of (the god) Elom in Greek Πύθων was one of the names of Lower Egypt and situated in the Wadi Tumul on a canal from the Nile to the Red Sea Suchoh (Egyptian Thake) was identical with it or was in its neighbourhood The site now Tell el Maskhuta has yielded several important monuments including the best preserved of the bilingual tablet of Darius which commemorated his work on the canal

**PITIGLIANO**, a town in Italy province of Grosseto Pop (1931) 5,115 It is the cathedral city of the bishopric named after the neighbouring town of Sovana and was originally a fief of the countship of Sovana which in 1193 came by marriage into the possession of the Orsini In 1410 Sovana was taken by the Siennese but the Orsini retained Pitigliano Gentile Orsini assuming the title of count In 156 the Medici of Florence seized part

of their territories and acquired the rest by exchange in 1500 The Orsini stronghold still stands in the town which is perhaps identical with the Etruscan Statonia

**PITLOCHRY**, village of Perthshire Scotland 28½ m NW of Perth by the LMS railway Pop (1911) 241 It lies on the left bank of the Tummel a little below the confluence of that river and the Garry 350 ft above the sea It is a tourist centre

**PITMAN, SIR ISAAC** (1813-1897) English phonographer was born at Frowbridge Wiltshire on Jan 4 1813 He started in life as a clerk in a cloth factory but in 1831 he was sent to a training college for teachers After eleven years of teaching in elementary schools he opened a private school in Bath In 1829 he took up Samuel Taylor's system of shorthand and became an enthusiast in developing the art of phonography In 1837 he drew up a manual of Taylor's system and offered it to Samuel Bagster (1771-1850) The publisher did not accept the work but suggested that Pitman should invent a new system (see **SHORT HAND**) of his own The result was his *Stenographic Soundhand* (1837) Bagster's friendship and active help had been secured by Pitman's undertaking to verify the half million references in the *Comprehensive Bible* and he published the inventor's books at a low price thus helping to bring the system within the reach of all Pitman established at Bath a Phonetic Institute and a *Phonetic Journal* for this purpose he printed in shorthand a number of standard works and his book *Phonography* (1840) went through many editions He was an enthusiastic spelling reformer and adopted a phonetic system which he tried to bring into general use In 1894 he was knighted He died at Bath on Jan 12 1897 Isaac Pitman's system revolutionized the work of reporting

His Life was written in 1902 by his brother Benn Pitman (1822-1911) and by Alfred Baker in 1908

**PIT PONY** The pit pony is usually a small pony—14 hands high and under—used for hauling the tubs for the conveyance of coal from the working face of the coal seam to a point variously termed the flat double parting station or landing where the tubs are made up into sets or trains and conveyed either by horses or more commonly by mechanical haulage to the shaft bottom That is to say the pit ponies ply between the face and flat bringing the full tubs out from the hewer and serving him with empty tubs

The use of pit ponies has decreased with the extended development of electrically driven haulage underground

The care and treatment of horses and ponies at mines in the United Kingdom are the subject of stringent provisions in the Coal Mines Act 1911 (third schedule)

**PIT SHAFT** *see* COAL AND COAL MINING

**PITT, THOMAS** (1681-1761) British East India merchant and governor of Madras usually called Diamond Fort. Born at Blandford Dorset on July 3, 1681. From his headquarters at Balasore he engaged in trade in opposition to the East India Company whom he opposed also in the law courts. Unable to check him the East India Company took him into custody in 1695 and in 1697 he became president of Fort St. George at Madras. While in India Pitt bought the fine diamond which was named after him in 1711 he sold his to the regent of France Philip duke of Orleans and it is now the property of the French government. During his stay in England Pitt acquired the manor of Old Sarum and for a short time he represented this borough in parliament. After his final return from India in 1710 he again became member of parliament for Old Sarum. He died at Swallowfield near Reading on April 8, 1761. His eldest son Robert was the father of William Pitt earl of Chatham (1709) and of Thomas Pitt (d. 1761) whose son became the first Lord Camelford his second son Thomas Pitt (c. 1688-1709) having married Frances (d. 1717) daughter of Robert Ridgeway 4th earl of Londonderry (d. 1714) was himself created earl of Londonderry in 1716.

*See* Sir C. N. Dalton *Life of Thomas Pitt* (1915)

**PITT, WILLIAM** (1759-1806) English statesman second son of William Pitt earl of Chatham and of Lady Hester Grenville was born at Hayes near Bromley Kent on May 8, 1759 in the year of the pinnacle of his father's glory. Both because of his extreme delicacy and because his father was an early critic of the public school system he was educated at home under the tutorship of the Rev. Edward Wilson of Pembroke Hall Cambridge and the earnest supervision of Chatham himself—a plan which tended to the intensive development of the child's unusual precocity. Before he was ten years old he was a good classical scholar at 15 he had composed a strange political tragedy *Laurentino King of Chersonese*. In Oct. 1773 in his 15th year he went into residence at Pembroke Hall Cambridge where his tutor was the Rev. Dr. George Pretyman (he changed his name in 1803 to Tomline) to whom Pitt in later years awarded the bishopric of Lincoln and at the last bequeathed his papers and who in return became his pupil's first biographer. Pitt had not been at Cambridge long when he fell seriously ill and was obliged to return home. It was then that the family physician Dr. Anthony Addison prescribed that generous consumption of port wine which was to become the habit of a life. He returned to Cambridge in July 1774 and in 1776 by the privilege of his birth as the son of a peer graduated as a master of arts without examination. That year saw the Declaration of American Independence and the next the battle of Saratoga. On April 7, 1778 Pitt was the witness of his father's last dramatic utterance in the House of Lords. A month later Chatham died. Pitt was left with an income of £300 a year, he began to keep his terms at Lincoln's Inn was called to the bar on June 12, 1780 and joined the western circuit. At the general election in September Pitt was defeated for the University of Cambridge but was returned for Sir James Lowther's pocket borough of Appleby. He entered parliament on Jan. 23, 1781 he was not yet 22 years old.

**Parliament**—Pitt was attached to that section of the opposition which had followed his father and was now led by Lord Shelburne. His maiden speech on Feb. 26 was made in support of Burke's Bill for economical reform and produced a series of famous eulogies. Lord North admitting it the best first speech he had ever heard and Burke with even greater prodigality declaring him not a chip of the old block but the old block itself. A year later when North's ministry was near its fall Pitt had the self-confidence to announce in the House of Commons (March 8, 1782) that should he conceivably be asked to join the new ministry he would never accept a subordinate position in it nor did he alter his mind when Rockingham shortly afterwards offered him certain well paid but unimportant posts and even though one of them—the vice-treasurership of Ireland—had been held by Chatham before him.

As a private member Pitt now supported a new version of

Burke's reform project a measure for shortening the duration of parliaments and another for destroying bribery at elections. On May 1 he presented his own motion for a select committee to inquire into the state of the representation. It was only by a narrow vote that he was defeated. Shortly afterwards the death of Rockingham on July 1 provided a new opportunity. The king appointed Shelburne as his choice for Lord John Campbell and Burke immediately returned to serve with him. Whereupon Shelburne turned to Pitt who on July 6 accepted the office of chancellor of the exchequer.

**The Shelburne Ministry**—The ministry was only to last until the following February. On Jan. 31, 1783 the preliminaries of the Peace of Versailles were signed and provided the opposition with a easy target. It was essential for Shelburne to obtain more support and on Feb. 11 by agreement with his chief Pitt visited Fox to invite him to return to the ministry. Fox replied that he would only serve on the condition that Shelburne resigned the premiership whereupon Pitt replied I did not come here to betray Lord Shelburne. The incident is important. It marks the beginning of the ceaseless political warfare between Fox and Pitt. It marks the end of the Shelburne ministry and the origin of the coalition between Fox and North. Speaking of North's Government only in the previous year Fox had declared: From the moment when I shall make any terms with one of them I will rest satisfied to be called the most infamous of mankind and he had loudly demanded their impeachment yet he who had poured his blistering scorn upon North's conduct of the war now joined with North in execrating the terms of the peace. The ministry was defeated (Feb. 1) and two days later Shelburne resigned. For a month the king sought to escape the coalition. But Pitt who was pressed to accept the Treasury preferred to bide his time and North could not be lured from Fox. On April 1 the Fox-North coalition under the nominal leadership of the duke of Portland took office.

**The Coalition Ministry**—On May 7 Pitt brought forward resolutions for checking bribery at elections disfranchising corrupt constituencies and increasing the number of county and London members of parliament. The resolutions were refused by 293 to 149. On June 2 he brought forward another bill which passed the Commons but failed in the Lords for reforming abuses in public offices. He instanced North's mysterious consumption of stationery which totalled £1,300 and contained an item of £340 for whipcord.

During September and October Pitt visited France—his only venture outside his own country. In November parliament reassembled and Fox immediately introduced his India bill. Passed in the Commons the measure was defeated in the Lords (Dec. 1) because George III plainly informed the peers at large through Lord Temple that he should regard anyone who voted for the bill as his enemy. The Government very properly refused to resign. Whereupon the king on Dec. 19 depending upon a barely literal interpretation of his constitutional rights but reflecting by accident the wishes of his people dismissed his ministers and appointed Pitt as first lord of the treasury and chancellor of the exchequer. The coalition had been jockeyed out of office and it is not surprising that the House received the news of Pitt's appointment with mirth. It is mistakenly generous however to suppose that Pitt assumed office from pure altruism and without a certain confidence in the future. The strident Opposition no longer represented its constituency and Pitt knew it and while they were wasting their breath deriding the boyish prank Pitt was converting the electorate—voters who were to be more valuable to him than the voters in the House of Commons. Almost as important the influence of the City and of the East India Company was on his side. Until the end of March he struggled on continually defeated in the House but steadily refusing to resign. Outside his popularity was growing while the action of the Opposition in threatening to oppose even the votes of supply cast on them the obvious accusation of factiousness. The hostile majority diminished daily until on March 8 Fox's "representation" was carried by only one vote. On March 24 parliament was dissolved. The essential business had been forced

through At the ensuing election some 160 of Fox's Ministers were rejected This was the answer to the charge of unconstitutional action throughout the struggle Pitt had in fact represented the nation Pitt was himself elected for Cambridge university which he represented for the rest of his life

### PITT'S FIRST MINISTRY

**Finance**—Finance was the first consideration The country was a heavy debt and the fiscal machinery was antiquated Pitt floated a loan of £6,000,000 of the floating debt offering the tender to public competition and funded £6,600,000 of the floating debt The loss to the revenue which had long resulted from the systematic evasion of the high protective tariffs he countered by a radical reduction of duties—that on tea being reduced from 119% to 1% To meet the loss he increased the window tax and many new taxes were instituted to touch the whole people But he withdrew the tax on raw cotton and pronounced it as his principle that manufactures in general ought to be free from taxes

Pitt who had been one of the earliest students of Adam Smith next attempted the establishment of free trade between England and Ireland The Irish accepted his propositions (Feb 7 185) but in England the measure was met by the organized opposition of vested interest prejudice and faction Pitt was obliged to alter his original scheme and in that form the Irish disappointed and inflamed by Fox's subtle tongue rejected it

In 1786 Pitt introduced his sinking fund a measure adapted from a scheme of Dr Richard Price (*qv*) Economically it was undoubtedly mistaken but it was believed to be a sovereign remedy and it at least inspired public confidence

On April 18 1785 Pitt brought forward a bill proposing to suppress 36 pocket boroughs and to transfer their members to increase the representation of certain towns and counties £1,000,000 was to be spent upon the purchase of the interests of the various owners The bill for which he eloquently pleaded was rejected by 248 to 174

**India**—Pitt's India Bill which had been rejected during the first struggle in the spring of 1784 was passed in the summer easily enough Pitt's bill unlike Fox's left the ordinary patronage with the directors of the company while passing to the Crown the political control Moreover he had the tact and the wisdom to consult the company and to present as a final draft a measure to which he knew they were prepared to agree The bill was not without serious defects—especially in its subordination of the governor general not only to his council but in all important concerns to the home Government Warren Hastings resigned at once and upon his return his conduct of the Government was called in question Pitt who had voted against the Rohilla charge (which was not carried) voted in favour of the Benares and the Begum charges His action decided the issue The motions were carried and the impeachment pursued Pitt has been heavily criticised for his conduct But the truth that Hastings had been a great administrator could not disguise the fact that here was a patent scandal which demanded inquiry Indeed Hastings through his agent in the House had himself originated the discussions and Pitt deliberately chose to support the Opposition in a matter where he honestly believed them to be right instead of following the usual custom of opposing whatever measure the Opposition proposed

**The Regency Question**—In Nov 1788 the king's illness provoked a crisis which might have ended Pitt's political career There was a traditional enmity between the Hanoverian monarchs and their sons and the whole influence of the prince of Wales (doubly hostile because Pitt would not pay his debts) was directed to the cause of the Whigs The king being insane it was essential to appoint a regent and Pitt was inevitably agreed that there could be no other candidate for the office than the prince of Wales The point at issue lay in the claim of Fox and his party that the prince had a prerogative right to the position Pitt claimed that he could only become regent by act of parliament and drew up that act so as to restrain the regent from making peers or granting pensions while the king's person and household and the patronage of the Crown were to be placed under the direction of

the queen The bill passed the Commons (Feb 5 1789) and while it was under discussion in the Lords the king recovered The situation had been dangerous for though the resolutions had been carried there had been much uneasiness among Pitt's followers Pitt himself believed that he would be unable to retain office and would have to resume work as a lawyer The London merchants at this time offered him £100,000 in recognition of his conduct but Pitt replied that no consideration on earth shall ever induce me to accept it At the general election of 1790 he obtained an increased majority In April 1791 by his Constitutional Act he arranged for the division of Canada into Upper and Lower Canada The following year he accepted the wardenship of the Cinque Ports which carried a salary of £3,000 a year

**Foreign Policy**—The first important act of Pitt's foreign policy—the commercial treaty with France—was complementary to his reorganization of the home finances The abandonment of useless trade restrictions was plainly to the benefit of both countries and Fox could think of no better ground of attack than to assert that France was the unalterable enemy of England to which objection Pitt replied that to suppose that any nation could be unalterably the enemy of another is weak and childish In 1787 there was trouble in Holland The Emperor Joseph II had been for some time preparing a labyrinthine scheme whereby he should consolidate his dominions by annexing Bavaria whose elector was to be compensated in the Austrian Netherlands The scheme was agreeable to France who was intriguing for the overthrow of the Dutch stadholder and complete influence in Holland War was only avoided after full preparations had been made (an expedition for instance was actually prepared for the capture of the Cape) because Prussia who was opposed to Joseph II's policy was at length persuaded to stand with England Upon Prussia's entry into Holland the Austro-Russo-French intrigue collapsed and the stadholder was restored In 1789 England was brought into conflict with Spain who had seized the British trading post at Nootka Sound Again war seemed imminent (over two millions sterling were spent in naval preparations) but Spain receiving no support in Europe was obliged to withdraw Less successful was Pitt's intervention in the Eastern question Catherine II of Russia was at war with Sweden and Turkey The Triple Alliance (of England Prussia and Holland) had gained a prestige which placed it in a position to work for the maintenance of the balance of power But though Austria's support was detached from Russia and Gustavus III made peace with Catherine the empress was not to be diverted from her ambitions in Eastern Europe She gained great success in 1791 and Pitt without adequate means of supporting his policy determined to prevent Russia from establishing her power in the Black sea He demanded that Russia should give up Oczakov but Oczakov meant nothing on earth to the British public and Catherine perceiving there was no force behind the ultimatum was unmoved by it Though armament credits had been voted Pitt was obliged to retire

Pitt had not at first anticipated that the French Revolution would involve England in hostilities In the spring of 1792 he was happily discussing finance prophesying the reduction of 25 millions of debt in the next 15 years and declaring in support of his vision that there never was a time when from the situation of Europe we might more reasonably expect 15 years of peace than we may at the present moment He had no intention of interfering in a matter which concerned France alone and indeed in its original conception he was not unsympathetic to the aims of the Revolution On Aug 10th the French monarchy fell and the English ambassador was recalled from Paris and Chauvelin in London could henceforward be only received unofficially But this was merely a question of diplomatic routine friendly relations were not strained until the French having already declared war upon Austria and Prussia followed the victory of Jemappes by occupying the Austrian Netherlands threatening Holland and overturning the treaties which governed the navigation of the Scheldt England was bound by treaty to support Holland and as she had been through the centuries she was not less insistently bound in this matter by her own interests The execution of the king and among the French people a rising tide of truculence swiftly fol

lowed. On Feb. 1 while Pitt was outlining the provocation which Britain had received from France the country was deep-chained yet another in the hope of a declaration of war. The real end of Pitt's life was to be spent in the shade of the revolutionary war.

**War**—The history of the wars with France is discussed under FRENCH REVOLUTIONARY WARS NAPOLEONIC CAMPAIGNS NAPOLEON FRANCE etc. It is only possible here to mention briefly the part that Pitt played in the organization of Europe. It has long been a current *cliche* to say that Pitt was a great peace minister and a poor war minister. But in Pitt's talent were indeed essentially suited to peace it is equally true that Napoleon was finally encompassed in disaster by the dogged determination of the English premier and after his death by the remembered influence of that resolution. To compare him with his father is to die. Chatham had every advantage. His allies were great commanders; his France was *etienne*. But revolutionary France was inspired with a fanatic hope and England's continental allies proved continually worthless. Year after year Pitt laboured to sustain his coalitions of the Powers; year after year the coalitions melted away before the victorious advances of the French. England who had no call to be anything but a member of a general European league against France was forced to be the inspiration as well financially as politically of the entire organization.

**Home Policy**—At home the war changed entirely the tranquil prospects of national wealth and prosperity. New voices were in the air—voices of political discontent and shortly the voices too of hunger. Pitt's policy at home at this juncture is of great importance. Because he never again brought forward the question of reform after his failure in 1805 and opposed it whenever it was proposed by others his sincerity has been openly called in question. His actions certainly demand some explanation. It is in the first place important to admit that there was as yet no national enthusiasm for reform; the cry had been raised largely in protest against the unconstitutional behaviour of the king and had been lulled since the declaration of peace; moreover those who had been foremost in urging economical reform had no such belief in the necessity of parliamentary reform. A statesman—especially one on whom practically the whole conduct of a Government devolves—can not persist in a measure which has been again and again rejected in one form or another. Pitt had a large majority. But the fact that he remained in office for so long has obscured the truth that he was to a very large extent dependent upon the caprices of that majority. A contemporary political estimate recorded the number of those gentlemen who would probably support his majesty's Government—roughly the Court Party—as more than three times the size of Pitt's personal party and there was a further shifting and entirely independent vote. For all his dominance of the House Pitt was sometimes defeated—over the Westminster petition (see FOX CHARLES JAMES) over Ireland over his proposals in 1786 to fortify Plymouth and Portsmouth. The demand for reform was not seriously supported in the House of Commons. More important still it was not as yet properly vocal outside its walls.

In 1792 Tom Paine's *Rights of Man* had been published suddenly jolting the English Radical movement into a new mind at the moment when the French doctrines were filtering into England in a fashion admittedly designed to provoke dissensions. The circumstances had become altered. Pitt's refusal to support the motion for the repeal of the Test and Corporation Acts in 1789 and 1790 was unintelligibly craven but when he refused to support Grey in 1792 he had excuse. The hurricane season had set in. Pitt allowed himself to be stampeded by a species of panic which was entirely unjustified by the facts. Talleyrand at this time remarked that those curiously deceived themselves who believed that England was on the verge of revolution. He was a more shrewd observer of truth—but it must be admitted that he had the advantage of looking at Britain not only in perspective but also dispassionately. Deceived or not Pitt declared that this was no time to revise a constitution and proceeded to punish severely any who should advocate reform doctrines. It was lamentable it was essentially unjust and there is but one excuse—the excuse which in sympathy has condoned many shameful

persecution when things are done in panic which are never justified by the patent facts but are believed to be necessary for profound reasons of state that can only be guessed at.

In 1795 and again in 1801 *Hall's Corpus* was suspended and banished to the suppression of edition followed. There succeeded the trials and transportations of men like Skirving, Margate, Gerald, Mair condemned for no more treasonable than an idea in parliamentary reform or universal suffrage. So the ideas of constitutional reform were ridiculed and suppressed. It is unpleasant to find that the records of the confiscated papers of the club reveal without exception nothing indicative of revolutionary organization. And yet in 1795 Pitt declared that were he to resign he would lose his head within a month. The circumstances were extraordinary and it is just to suppose that Pitt was honest; he was not the less grievously wrong.

It was not long before the pain of war was felt in England. Pitt had based his confidence in a short period of war upon the pathetic belief that France would be financially incapable of sustaining a prolonged struggle. But the war advanced and Pitt's subsidies were swallowed up upon the Continent by allies who made little or no return for them. The nation's debt mounted. The coalition crumbled. More money to buy more allies was needed. In 1795 after a season of bad harvests Pitt had to ask for a loan of 15 millions and to increase the general taxation. Shortly afterward followed the legacy duties. In 1797 taxation was increased by two million; the next year produced the income tax.

**Ireland**—One of Pitt's major pre-occupations was still Ireland. He had failed in 1785 but he never ceased to plan for the final consummation of his hopes. In 1793 Pitt forwarded the passage in the Irish House of Commons of the Catholic relief bill but in 1794 he suffered disappointment when Irish opinion was again alienated by the position he was forced to adopt against the antics of Lord Fitzwilliam who had been made lord lieutenant as a concession to the Portland Whigs who had entered the ministry in that year. Fitzwilliam and his party were anxious for a broad policy of reform and emancipation but Pitt had laid down a cautious line of action and it had been determined that Fitzwilliam should do nothing without the consent of the cabinet. But by an open breach of a most solemn promise he proceeded to dismiss the Irish Tory officials and without authorization to promise widely the immediate prospect of a full emancipation. Fitzwilliam was recalled and Ireland left to nurse an angry grievance. The whole bungling led directly to the disasters which followed the state of semi-civil war in 1797 and the rebellion of 1798 and that disaffection which could welcome the French invasion. The union of Ireland and England which he had sought earlier for the mutual benefit of both countries was now imperative as a solution to a state of war. On Jan. 3, 1799 Pitt brought forward his proposals for a union of the two countries. Emancipation was not promised (the hostility of George III's eccentric conscience precluded the suggestion) but the hope was held out that this would follow in due course. The bill was pressed through the Irish parliament by Cornwallis the viceroy and Castlereagh the secretary for Ireland. The distribution of titles and money played some part in this and more than a million pounds was expended in compensation to the holders of suppressed rotten boroughs. However open to moral criticism the latter decision may have been it was essential to the support of the bill and it destroyed an entirely dishonest system of representation. As for the measure of the general corruption that has at least been overestimated and in so far as material persuasion was adopted it must be remembered that bribery in the Irish parliament was a deeply respected tradition. Moreover it must have been patent to the guiding minds in Ireland that the present state of affairs was impossible and the possible benefits of the union for instance to trade were obvious. The bill having passed the Irish parliament in 1800 the first united parliament met in Jan. 1801. Pitt had now to enlarge his policy and once more the solution of Ireland's troubles was tragically postponed. Pitt had not promised emancipation but those who had voted for the measure had been led to expect that it must follow. With a secrecy which

was perhaps unwise but understandable in the circumstances Pitt drew up his preliminary suggestions for the abolition of religious tests the commutation of tithes and provision for Catholic and dissenting clergy. The plan was opposed in the cabinet principally by Lord Loughborough the chancellor who reported the matter to the king. George was enraged and adamant against the proposals and on Feb. 5 accepted the resignation which Pitt had tendered on Feb. 3. Immediately afterward the situation was complicated by the king's relapse. During his temporary insanity Pitt retained office until his recovery in July 1801. On March 14 many bitter things were spoken of him. Once again he was accused of betraying his cause. But he had boldly brought forward his reforms and his resignation followed upon their veto. Had he pressed his legislation the king would have persisted in his opposition moreover with the war going extremely ill it was not the moment to precipitate a domestic crisis. His promise to George never again to introduce the subject during the reign was sentimental not necessary and politically unwise. But he made it because the king had accused him of causing his illness and after all he might reasonably expect that the reign would be shortly finished. That Pitt intended to return to the fullest implications of his project is certain. But he himself had only five more years to live.

1801-1806

**Retirement**—Henry Addington who was called upon to lead the Government had been universally praised as an expert speaker of the House of Commons but he was no statesman. Pitt promised to do all he could to support Addington and generously assisted in the conduct of negotiations for the Peace of Amiens. These terms which Grenville branded as disgraceful and ruinous appeared in general highly satisfactory to Pitt. Though he had long been anxious to conclude any peace which was at all reasonable it is difficult to justify him in supporting a peace which recognized the failure of the coalitions to establish the independence of the Netherlands—which had been the ostensible *casus belli*. On the other hand there is evidence that Pitt was conscious of the unstable nature of the peace and foresaw that a greater struggle was probable. The public supported the peace and during the discussions a severe vote of censure upon Pitt was rejected and a counter motion passed by 211 to 5 declaring that he had rendered great and important services to his country and deserves the thanks of the house. He retired now from parliament for the space of about a year living largely at Walmer Castle where as warden of the Cinque Ports he organized with great diligence and enthusiasm a local volunteer force. The brief interval gave an opportunity too for the examination of his debts. Pitt who had been so astute in public economy was careless of his own. He who had scornfully demanded an explanation of Lord North's expenditure of £340 of public money on whips had himself to account for the grotesque item of £600 for hats. Both thoughtless and generous Pitt was the victim of swindlers and in 1800 already owed £45 000 despite the fact that he had received a salary of over £10 000 for many years. He nevertheless refused an offer of £100 000 from the citizens of London and a gift of £30 000 from the king though he accepted £11 000 as a loan from a committee of private friends he was obliged to sell his house Holland House.

Addington had won a great victory at the general election but it was not long before his policy began to drift towards perilous courses. When it was clear that a rupture of the peace was imminent Pitt was approached but he no longer felt that Addington's policy could receive his honest support and later negotiations provoked so wide and insistent divergencies of mind upon the personnel of a possible cabinet as to make agreement impossible and even to interrupt an ancient friendship. War broke out again on May 16 1803. Against the insufficient programme of the ministry Pitt opposed a vigorous policy in a speech (May 23) which provoked the enthusiasm of all parties. But while the cleavage was growing plainer and plainer Pitt yet refused directly to oppose Addington to whom he had promised his support. The situation was becoming increasingly serious. In the face of the

growing danger of invasion the measures of the Government were entirely inadequate and early in 1804 Pitt was forced into stronger opposition. Complicated once again by a threatened relapse of the king negotiations for a stronger administration were protracted. The ministry was doomed when a motion of Fox for a committee of enquiry into the national defences was powerfully supported by Pitt and after some days of negotiation he attained a chancellor of the exchequer and first lord of the treasury on May 10.

**Second Ministry**—Pitt's second term of office was marked by no great enterprise of governance. The war alone absorbed his energies. The labour and the inspiration of the great European coalition again rested exclusively upon Pitt and his health now gravely undermined was beginning to break beneath the strain when early in April 1805 he suffered the pain of witnessing the public disgrace of his old friend and colleague Dundas (Lord Melville 1790). The battle of Trafalgar (Oct. 21) destroyed the possibility of invasion but the year closed in disaster. The capitulation of Ulm (Oct. 20) was succeeded by Austerlitz (Dec. 2). At first Pitt was able to doubt the full implications of the news but gradually as despatches authenticated the reports he came to realize that the mighty coalition was hopelessly broken. England had saved herself by her exertions he had remarked at the Lord Mayor's banquet in the previous November she would save Europe by her example. And now Napoleon stood without a force to oppose him upon the whole continent and Pitt with prophetic accuracy was brought to the bitter admission that the map of Europe would not be wanted these ten years. On Jan. 3 1806 he died and if his last words were not 'My country! How I leave my country!' his thoughts can have been none other.

**Constitutional Importance**—The period of Pitt's government covered a supremely important moment of political transition. It was also a period of a not less important crystallization of British constitutional doctrine. It would be wrong-headed to attribute that growth too strongly to Pitt's political acumen. Both the length and the critical instant of his ministry made development natural and inevitable. He was placed in the position of leadership at precisely the tactical moment. The fruit was ripe but it was the harvest of a century of other men's labours. Pitt was the first Hanoverian minister to appeal definitely from the vote of the House of Commons to the vote of the constituencies and throughout his career his strength was derived from the public confidence. In his colleagues Pitt appeared to prefer industry to genius. If this was partly because of an exaggerated sense of his own authority it must also be remembered that the choice was also one of necessity. Pitt did overshadow his colleagues—but it was no difficult task. The result contributed to his general theory that the independence of Government departments was impossible. They must rather be bound together with a corporate policy responsible to the Crown under a common allegiance to the prime minister. Walpole who is generally considered the first prime minister denied the title and was succeeded by Government which could only exist under the leadership of duumvirates and triumvirates. Pitt not only claimed the title of prime minister but declared that the office was essential to sane government. In 1803 when negotiations were on foot for a ministry in which the authority should be shared by himself and Addington he stated that it was an absolute necessity that there should be an avowed and real minister possessing the Chief Weight in the Council and the principal place in the confidence of the King in that respect there can be no rivalry or division of power. It must rest in the person generally called *first minister* who ought to be at the head of the finances. And if a difference of opinion arose the sentiments of the minister must be understood to prevail. This view moreover was widely understood by contemporary commentators. In 1794 when Lord Fitzwilliam went to Ireland he was pledged to support the Government considering Mr Pitt as the *Prime Minister* without whom no material measure as to *Things or persons* is to be concerted or done (*Carlisle Papers*) and the Glenbervie Diary (Dec. 30 1798) corroborates this language. In everything Pitt laboured to assert the authority of the cabinet, and of the premier within the cabinet. He was the king's

teachers and 552 students (1936). In the Allegheny district are the Allegheny Theological seminary (United Presbyterian 1853) the Western Theological seminary (Presbyterian opened 1877) and the Reformed Presbyterian Theological seminary (1810). Under the new school code (1911), a board of education consisting of 15 members appointed by the judge of the common pleas courts controls the public schools. There were (1931) 11 high schools with 905 teachers and 955 pupils, one Teachers Training school, six special schools, 134 elementary schools with 1666 teachers and 63464 pupils and evening schools with 1955 pupils. The parochial schools had 30 high schools, 6 teachers and 3515 pupils and 16 grade schools, 1017 teachers and 5545 pupils, and there are many private schools and academies among them Shadyside academy. The Henry C. Frick Education Commission has an endowment of several millions for the improvement of teaching in the public schools.

The *Pittsburgh Gazette* (1786) was probably the oldest news paper west of the Allegheny mountains and was (1906) consolidated with the *Times* (1819) under the name of *Gazette Times* and recently (1927) consolidated with the *Post* (Sunday 1820 daily 1841) under the name *Post-Gazette* the only morning paper. The evening papers are *Sun-Telegraph* and the *Pittsburgh Press* which purchased and discontinued (1933) the *Dispatch* (1846) and the *Leader* (Sunday 1864 daily 1870). A German daily weeklies in Slovak, Italian, Polish and five other languages and iron steel building coal glass agriculture and other trade journals are published in the city. In Pittsburgh are published the *Presbyterian Banner* (1814 the second oldest religious paper in the United States) the *United Presbyterian* the *Christian Advocate* the *Catholic Observer* the *Pittsburgh Catholic* and other weeklies.

The oldest hospital was the Reineman (1893) for maternity cases made the University maternity hospital (1893) and transferred to Magee hospital (1910) the latter with the Children's Eye and Ear and Presbyterian forming the new medical Centre of the University of Pittsburgh. Other hospitals are Municipal (1878) Tuberculosis Homeopathic Montefiore Passavant Rosalia Maternity St. Johns St. Joseph's St. Margaret Memorial South Side West Penn. Allegheny General Columbia in charge of United Presbyterian Women's Association and the Sisters of Mercy. Mercy hospital Sisters of St. Francis St. Francis hospital and the Sisters of Charity Pittsburgh hospital. The Western Pennsylvania schools for the deaf and for the blind are located in Pittsburgh and many of the hospitals, schools, homes and charitable institutions, non-sectarian, are in part maintained by the State. The Y M C A had 12 branches and the Y W C A (metropolitan) had six branches (1937) and there were over 550 churches, 33 all-year playgrounds, 19 public swimming pools, 59 parks and over 200 social and welfare agencies.

**Industry and Commerce**—Pittsburgh is in the midst of the most productive coal fields in the country; the region is also rich in petroleum and natural gas. The city is on one of the main lines of communication between the east and the west; is the centre of a vast railway system and has freight yards in and outside the city with a total capacity for more than 60,000 cars. Its harbour has a total length on the three rivers of 27.2 m. and an average width of about 1000 ft. and has been deepened by the construction (in 1877-85) of the Davis Island dam by dredging under a Federal project of 1899. This dam has been superseded by the Emsworth fixed dam. Slack water navigation has been secured on the Allegheny by locks and dams (1890-1896 *et seq.*) at an expense up to July 1909 of \$1,658,804 and up to that time \$263,625 had been spent for open channel work. By 1936 eight of nine projected dams had been fully completed. The Monongahela from Pittsburgh to the West Virginia State line (91.5 m.) was improved in 1836 *et seq.* by a private company which built seven locks and dams; this property was condemned and bought for \$3,761,615 by the United States Government in 1897 and under the project of 1899 for rebuilding three of the locks and enlarging another and that of 1907 for a new lock and dam and for other improvements \$2,675,692 was spent up to July 1909. Since then six of these have been entirely rebuilt and changed to

two chamber locks and eight more locks have extended the facilities to Fairmont 13 miles away. Coal is brought to the city from the coal fields by boats on the Allegheny and Monongahela rivers as well as by rail and great fleets of barges carry coal and other heavy freight such as steel rails, cotton ties, sheet iron wire and nail down the Ohio in the winter and spring. A ship canal to provide water communication between Pittsburgh and Lake Erie has been projected and is awaiting the approval of the army engineers. The railways have a heavy tonnage of coal, coke and iron and steel products and a large portion of the iron ore that is produced in the Lake Superior region is brought to Pittsburgh. In 1935 the river traffic amounted to 3,164,444 tons valued at \$14,496,906. Most of the exports valued at \$1,355,803 were carried on barges down the Ohio. Pittsburgh is also a port of entry its 9.5 imports amounting to \$5,064,103.

According to the census of manufactures for 1933 the factories 981 in number situated within the city gave employment to 354,676 workers paid in wages the total sum of \$33,956,066 and manufactured products valued at \$193,085,111. The leading industries in order of the value of their products in 1935 were Iron and steel, steel works and rolling mills \$95,668,112 bread and other bakery products \$36,815,3 foundry and machine shop products \$34,941,603 printing and publishing newspaper periodical book and job \$33,309,161 slaughtering and meat packing \$8,558,03 confectionery \$11,115,599 bolts nuts washers and rivets \$9,54,06. Other manufactures included electrical machinery and supplies, car shop construction and repairs, coffee and spice roasting and grinding, ornamental iron work, brass, bronze and non-ferrous alloys, paints and varnishes and planing mill products.

In finance Pittsburgh occupied seventh place in bank clearings with \$5,457,189.8 in 1935 and (March 4, 1936) had national bank deposits \$5,387,441.94 State bank deposits \$1,076,378.45 and trust and savings deposits \$4,398,197.39. In Pittsburgh or the immediate vicinity are the more important plants of the United States Steel corporation including that of the Carnegie company and the Jones and Laughlin Steel corporation, one of the largest independent steel companies in the United States. Here too are the plants of the Westinghouse company for the manufacture of electrical apparatus of air brakes invented by George Westinghouse (born 1846) and of devices for railway signals which he also invented. In the Allegheny district the H. J. Heinz company with its 57 varieties has its main food preserving plant, the largest establishment of the kind in the country.

**Government**—The Pittsburgh charter of 1816 vested the more important powers of the city government in a common council of 15 members and a select council of nine members and until 1834 the mayor was appointed annually by these city councils from their own number. By the Wallace Act of the State legislature in 1874 a form of government was provided for cities of three classes and Pittsburgh became a city of the second class (population between 100,000 and 300,000) under the Act of 1895 a new classification was made under which Pittsburgh remains in the second class. An Act of 1887 had amended the provisions of the Wallace Act in regard to second class cities by changing the terms of select councilmen from two to four years and of common councilmen from one to two years. In 1901 a new act was passed for the government of cities of the second class. It provided that the executive be a city recorder; this provision was repealed in 1903 when the title of mayor again came into use. By act of legislature (1911) the former common and select councils were superseded by a small council of nine members elected by general vote of the entire city. The mayor elected by the people for a term of four years continued to appoint the heads of departments (public safety, public works, assessors, treasurer, law, welfare, health, supplies, etc.) and the comptroller also continued to be elected by popular vote. By a two-thirds vote the council may pass resolutions or ordinances over the mayor's veto. The department of public safety controls the bureaux of police, fire, building inspection, electricity and general office; the department of public works controls the bureaux of water, highway and sewers, property, parks, recrea-

tions tests lights deed registry bridges and construction The mayor appoints the members of the civil service commission Through a city planning commission recommending zoning ordinances and through a board of adjustment the height and character of all buildings are controlled A bureau of traffic relief and a traffic commission were created in 1914 and in 1915 a department of city transit charged with the regulation of traffic conditions and with the matter of recommending subways and a comprehensive system of rapid transit lines for the entire city In 1936 the taxable valuation was \$6 069 550 for land and buildings and the tax rate was 20 60 mills on land 10 30 on buildings and 11 5 for schools The water supply of Pittsburgh is taken from the Allegheny river and pumped into reservoirs the highest of which in Highland park is 36 ft above the river the supply is filtered For the history of Pittsburgh see PENNSYLVANIA (S B McC)

**PITTSFIELD**, a city of western Massachusetts USA the county seat of Berkshire county on Federal highways 1 and 6 and served by the Boston and Albany and the New York New Haven and Hartford railways Pop (1900) 41 763 (20% foreign born white) 1930 Federal census 49 677 It occupies 41 4 sq m at an altitude of 1000 ft in the midst of the Berkshire hills Three branches of the Housatonic river wind through the city uniting about a mile from the central green Within its limits are the villages of Barkerville Coltsville Junction Pontoosuc Shaker Stearnsville Tacomic Tillotson and West Pittsfield and the whole or parts of five lakes (Pontoosuc Onota Morewood Silver and Richmond) It is a well built city with dignified public buildings substantial business blocks modern schools shaded residential streets and on the outskirts large manufacturing plants The assessed valuation for 1917 was \$5 809 775 Pittsfield is a tourist centre and a resort for winter sports Its manufacturing industries are large and distinctive with an output in 1917 valued at \$50 191 653 They include a plant of the General Electric Company making monster transformers and other machinery and devices where artificial lightning was produced in 1917 and the mill that makes all the paper used for the US bank notes and Government bonds The oldest industry (still one of the most important) is textile manufacturing chiefly woollen goods Fine stationery paper mill equipment machine tools spool silks and silk braids are other leading products The first settlement within the present boundaries of Pittsfield (Boston Plantation or Pontoosuc) made in 1743 was soon abandoned because of trouble with the Indians It was revived in 1749 and in 1761 was incorporated as the town of Pittsfield named in honour of the elder William Pitt The town was chartered as a city in 1889 Shaker Village was settled (by Shakers) about 1790 Elkanah Watson (1758-1842) while living (1807-16) at what is now the Country club introduced the merino sheep

**PITTSTON**, a city of Luzerne county Pennsylvania USA on the Susquehanna river just below the mouth of the Lackawanna about midway between Scranton and Wilkes Barre It is served by the Central of New Jersey the Delaware and Hudson the Erie the Lackawanna the Lackawanna and Wyoming Valley and the Lehigh Valley railways Pop (1920) 18 497 (26% foreign born white about half from Italy) and in 1930 18 246 and 7 940 (1930) in the adjoining borough of West Pittston Within 2 5 m of the city hall about 60 000 persons were living in 1928 Pittston is in the midst of the anthracite coal region Fire clay also abounds The city has paper silk and knitting mills terra cotta works brass foundries cigar and cut glass factories and the Lehigh Valley railroad employs 1200 men It was one of the five towns founded in the Wyoming valley by the Susquehanna company of Connecticut and was named after the elder Pitt It was settled about 1770 incorporated as a borough in 1803 and chartered as a city in 1894

**PITUITARY EXTRACT or PITUITRIN:** see ANIMAL EXTRACTS

**PITYRIASIS VERSICOLOR**, a skin disease consisting of patches of brown discoloration mostly on the front of the body, and often attended with itching, especially after exercise The epidermis is scaly over the patch, and among the debris there may

be seen minute oval points of a vegetable parasite the *Microsporon furfur* The disease is mostly one of adults found all over the world and not associated in any special way with poor general health The treatment consists of rubbing in an ointment of potassium sulphide or one of the mercurial ointments or using ultraviolet rays habitually

**PIURA**, a coast department of northern Peru with area 15 9 qm pop (est 1911) 300 000 The department includes mountainous areas in the north (Cerros de Amatope) and east (cordillera sierrita) and a great desert (Sechura) in the south The chief river is the Chira a permanent stream and the Piura Crops are grown with the aid of irrigation as there is rainfall only at intervals of years Cotton growing is the leading industry in the irrigated valleys stock raising in the sierra The cultivation of *aspero* (full rough cotton) is peculiar to this department the product of a large bush and is known as vegetable wool (see PERU Agriculture) There are gins and factories for making cotton seed oil and cake also a crushing mill for castor beans which produces about 6000 al of castor oil annually Other crops include rice sugar tobacco maize potatoes yuca beans cacao and fruits all of which are consumed locally Sierran cattle are fattened in the upper valleys Goats are raised extensively Charcoal is made from the wood of the algaroba tree Though mineral deposits are widespread petroleum is the only one exploited It now heads the list of Peruvian exports and the only producing oil fields in the republic are in the department of Piura and the adjoining province of Tumbes They lie along the north western coast a narrow belt about 60 m in length The two chief operating companies are in Piura the International Petroleum Corporation a subsidiary of the Standard Oil Company whose chief field is Negritos 40 m north west of Paita produces about 80% of the national output (1 140 000 tons in 1926) and has a modern refinery at its port Talara The Lobitos Oil Company 10 m north of Talara formerly British now Peruvian produced 271 000 tons in 1916 shipped via Talara to the United States and Canada for refining About 15% of total production is consumed in Peru largely as crude oil by railways A standard gauge railway runs from Paita (qv) to Piura (58 m) by way of Sullana a distributing centre for southern Ecuador and narrow gauge railways connect the oil fields with Talara Roads are under active construction and sections of the coast highway and of the road across the Andes from Paita to the Amazon are finished Piura capital of the department pop (estimated 1920) 15 000 is on the Piura river 164 ft above sea level It was founded by Pizarro in 1532 on a slightly different site It has electric lights telephone and telegraph banks theatres superior court secondary schools and an excellent hospital Catacaos 6 m south of the capital is the centre of the Panama hat industry Hats are woven from leaves of *toquilla* palm (*Carludovica palmata*)

**PIUS I**, pope from about 141 to 154 He was the brother of Hermas author of the *Shepherd*

**PIUS II** (Aeneas Silvius de Piccolomini known in literature as Aeneas Silvius) pope from 1458 to 1464 was born on Oct 18 1405 at Corsignano (later called Pienza after him) near Siena His family claimed to trace descent from Romulus The eldest of 18 children he worked on the farm with his father until a priest enabled him at the age of 18 to go as a poor student to Siena where he divided his time between severe humanistic studies and sensual pleasure He was attracted to Florence by the teaching of Filelfo He became secretary to Domenico Capranica bishop of Fermo and went with him to the Council of Basle where he stayed several years (1431-35) changing masters whenever he could improve his position He was engaged on various errands some of them dangerous they included a long journey to England and Scotland on secret diplomatic business In 1436 he was back at Basle and, although a layman, obtained a seat in the council and exercised considerable influence Aeneas took an active part in the council after it was transferred to Florence, and though he still declined to take orders, he was given a position on the conciliar conclave which elected Amadeus of Savoy as pope under the title of Felix V In return for his

civice Felix made Aeneas popular try

A new period of his career opened in 1447 when he was elected by the council of the prince of the Elector of Mainz. He met Frederick III of Germany who made him chancellor and his private secretary. He married his wife with the chancellor K. p. Selk at Vienna one of whose daughters he celebrated in *Lucetta and Eurilla* a novel in the style of Boccaccio. At this period he also wrote his witty but immoral play *Christus*. In 1446 he took order as subdeacon and wrote that he meant to return to his native Venus for Bacchus. Aeneas was useful to Frederick as a diplomatist and married to give all parties the impression that he was the devoted advocate of each. He took an important part in the diet of Nuremberg (1444) and in 1445 made his peace with Eugenius. At the diet of Frankfurt (Sept. 1446) Aeneas modified the hostility of the elector to pope and emperor. The new pope Nicholas V made him bishop of Siena and for his service in negotiating the concordat of Aschaffenburg in 1448 he was made prince of the empire and cardinal.

The death of Calixtus III (who succeeded Nicholas V) occurred on Aug. 5 1458. After a hot fight in the conclave Aeneas was elected and took the title Pius II with a remuneration of Virgil's pious Aeneas. The humanists hailed his election with joy and flocked around to secure a share of the good things but they were bitterly disappointed. A Pius did not prove himself the liberal and indiscriminate patron they hoped. The fall of Constantinople in 1453 made a deep impression upon Pius and he never ceased to preach the crusade against the Turk. In Sept. 1459 he opened a congress at Mantua to promote the crusade but both the French and the Germans were annoyed with him for different reasons and he received little support. He believed that the decline in the papal influence was due to the usurpation of power by the councils and he now issued (Jan. 1460) the bull *Execrabilis et in pristinis temporibus inauditus* in which he condemned as heretical the doctrine that the councils were superior to the popes and proclaimed the anathema against any one who should dare to appeal to one.

While Pius was at Mantua war broke out between the French and Spanish in southern Italy and a rising of the barons devastated the Campagna. Hurrying back to Rome Pius succeeded in quelling the disorders. This measure still further alienated the pope from the French with whom he was at that time negotiating for the abrogation of the Pragmatic Sanction. When Louis XI came to the throne (Nov. 1461) he sent to Pius saying that he had abolished the Pragmatic Sanction hoping in return to get the kingdom of Naples for his countryman Rene of Anjou. As Pius continued to support Ferdinand Louis retaliated by reasserting the ancient liberties of the Gallican Church. At the same time a serious quarrel with the Germans prevented anything being done towards a crusade. George Podiebrad king of Bohemia was plotting to depose the emperor Frederick III who was supported by Pius. Diether archbishop of Mainz took the side of Podiebrad and replied to Pius's measures by appealing to a general council. He was declared deposed by the pope but kept his seat and in 1464 compelled the pope to recognize him again. The quarrel with Podiebrad who was accused of supporting the Utraquist heresy continued with increasing bitterness but without any decisive result until the death of Pius. In the meantime the pope did what he could to further the cause of the crusade. The discovery of alum mines at Tolfa gave him an unexpected pecuniary resource and to stimulate the zeal of Christendom Pius took the cross on June 18 1464. He set out for Venice where he intended to sail for the East but he was attacked with a fever and on Aug. 14 1464 he died.

Pius II was a voluminous author. Besides poems a novel and a play he wrote a number of orations, which were considered models of eloquence in their day. The tale of *Euryalus and Lucretia* was translated into many languages (Eng. 1560), and his Latin poems *Miseriae curialium* (Rome 1473), were read throughout Europe. Alexander Barclay translated some of them in *Certaine Eglogues* (1548?) repr. by Spenser Society (1885). His most valuable work however is his *Pii II Com-*

*mentariorum memorabilium quae temporibus suis contigerunt* a history of his time told in an interesting and rational manner. Also there is a *Chronographia et Asiae et Europae scripturae* of which a complete edition was published at Venice in 1502 and *Historia Bohemica* (Colo. 1555).

PIUS III.—The letter of Pius II are in process of publication by I. Wolkstein *Der Brief des Pius II an die Sicilianer* (Venedig 1900) in *Monumenta Germaniae Historica*. The Commentaries were published in 1542 at Lyon by Pius himself and completed by J. Gobeilinus. His other works are found in *Aeneas Silvii opera omnia* ed. I. Hönigsdorff (Leipzig 1851). See also Herzog, Hauck *Realencyclopädie* (1905) vol. 1, where a full bibliography will be found. *Index Pii II* (1904) L. *Index Historiae de Popes from the Close of the Middle Ages* (En. trans. 1906 vol. 11) M. Lucius *Pius II and Ludwig XI von Frankreich* 1461-6 (1913).

PIUS III (Francesco Nanni Todeschini Piccolomini) pope from Sept. 2 to Oct. 18 1503 was born at Siena on May 9 1459. When only 3 years of age he was made archbishop of Siena and cardinal deacon of St. Eustachio by his uncle Pius II who permitted him to assume the name and arms of the Piccolomini. He was employed by subsequent popes in several important legations as by Paul II at the diet of Regensburg and by Sixtus IV to secure the restoration of the ecclesiastical authority in Umbria. He opposed the policy of Alexander VI and was elected pope amid the disturbances consequent upon the death of the latter through the influence of Cardinal della Rovere afterwards Julius II. Pius was a man of blameless life and would doubtless have accomplished much had he lived. His successor was Julius II.

PIUS IV (Giovanni Angelo Medici or Medighino) pope from 1559 to 1565 was born at Milan on March 31 1499. He began his career as a lawyer but later entered the service of Paul III who made him a cardinal in 1549. In the protracted conclave that followed the death of Paul IV the election of Pius (Dec. 25 1559) was due to a compromise between the Spanish and French. In temperament Pius was affable vivacious convivial. He was moreover astute diplomatic and experienced in affairs. He allowed the reform movement initiated by Paul IV free course but tried to repair certain injustices of Paul IV and mitigated some of his extreme decrees. But to the nephews of Paul he showed no mercy they were charged with various crimes, condemned upon testimony of suspicious validity and executed on March 5 1561. With England lost to the papacy Germany overwhelmingly Protestant and France on the verge of civil war, Pius realized how fatuous was the anti-Spanish policy of his predecessor. He therefore recognized Ferdinand as emperor and conciliated Philip II with extensive ecclesiastical privileges. But subsequently antagonized by Philip's arrogance he assisted France with troops and money for use against the Huguenots.

After a suspension of ten years the council of Trent reconvened on Jan. 18 1562. Among the demands presented by the various nations were the recognition of the equality of the episcopate communion in both kinds clerical marriage and the use of the vernacular in Church services. It required all the pope's diplomacy to avoid compliance on the one hand and a breach with the powers on the other. Thanks to Morone and Borromeo however he achieved his end. The council was dissolved on Dec. 4 1563 and its decrees and definitions confirmed by the pope (Jan. 26 1564), who reserved to himself the sole right of interpretation and took various measures for enforcing its decisions.

After the termination of the council Pius indulged his desire for ease and pleasure to the great offence of the rigorists. Pius fortified Rome and contributed much to the embellishment of the city—among other works the church of Sta. Maria degli Angeli in the Baths of Diocletian, the Porta Pia, the Villa Pia in the

Vatican C rd ns and th Palace of the Con ervatori He died on Dec 9 1565 and was succeeded by Pius V

**PIUS V** (Michele Ghisleri) pope from 1566 to 1572 was born on Jan 17 1504 in the Milanese At the age of fourteen he became a Dominican monk He was appointed inquisitor in Como where his zeal provoked such opposition as to compel his recall (1550) The chief inquisitor Caraffa convinced of his able straightway sent him upon a mission to Lombardy and in 1551 appointed him commissary general of the Holy Office When Caraffa became pope Ghisleri was made bishop of Nepi and Sutri cardinal (1557) and finally grand inquisitor In this office he was continued by Pius IV whom however he antagonized by his censoriousness and obstinacy But after the death of Pius IV the rigorists led by Borromeo had no difficulty in making him pope (Jan 1 1566) Retaining his ascetic mode of life Pius immediately began the work of reform Decrees and ordinances were rapidly issued the papal court became a model of sobriety prostitutes were driven from the city or confined to a certain quarter penalties were attached to Sunday desecration profanity and animal baiting clerical residence was enforced conventuals were compelled to live in strict seclusion according to their vows catechetical instruction was enjoined A new catechism appeared in 1566 followed by an improved breviary (1568) and an improved missal (1570) The use of indulgences and dispensations was restricted and the penitential system reformed

Pius was the avowed enemy of nepotism One nephew it is true he made cardinal but allowed him no influence the rest of his relatives he kept at a distance By the constitution *Admonet nos* (March 29 1567) he forbade the reinvestiture of fiefs that should revert to the Holy See and bound the cardinals by oath to observe it In March 1569 Pius ordered the expulsion of the Jews from the States of the Church For commercial reasons they were allowed to remain in Rome and Ancona but only upon humiliating conditions In February 1571 the Umiliati a degenerate monastic order of Milan was suppressed on account of an attempt upon the life of the archbishop Carlo Borromeo

The rules governing the Holy Office were sharpened old charges long suspended were revived rank offered no protection but rather exposed its possessor to fiercer attack none were pursued more relentlessly than the cultured among whom many of the Protestant doctrines had found acceptance princes and states withdrew their protection and courted the favour of the Holy See by surrendering distinguished offenders Cosimo de Medici handed over Pietro Carnesecchi (and two years later received in reward the title of grand duke Sept 1569) Venice delivered Guido Zanetti Philip II Bartolome de Carranza the archbishop of Toledo In March 1571 the Congregation of the Index was established and hundreds of printers took flight to Switzerland and Germany The regret of Pius was that he had sometimes been too lenient He spurred Philip II on in the Netherlands and commanded the utter extermination (*ad internecionem usque*) of the Huguenots he protested against the tolerance shown by the emperor One of his cherished schemes was the dethronement of Elizabeth whom he excommunicated and declared a usurper (Feb 25 1570) but he had to content himself with abetting plots and rebellions He effected an alliance with Spain and Venice against the Turks and contributed to the victory of Lepanto (Oct 6 1571) Pius died on May 1 1572 and was canonized by Clement XI in 1712

See Ciaconius *Vitae et res gestae summorum pontiff rom* (Rome 1601-02 a contemporary of Pius) *Acta sanctorum maij* tom 1 pp 616 seq containing the life by Gabuzio (1605) based upon an earlier one by Catena (1586) Falloux *Hist de St Pie V* (3rd ed Paris 1858) eulogistic Mendham *Life and Pontificate of St Pius V* (London 1832) a bitter polemic The life of Pius has also been written by Fuenmayor (Madrid 1595) Paolo Alessandro Maffei (Rome 1712) and by T M Granello (Bologna 1877) His letters have been edited by Catena (*vide supra*) Goubau (Antwerp 1640) and a select number in a French translation by de Potter (Paris, 1826)

**PIUS VI** (Giovanni Angelo Braschi) pope from 1775 to 1799 was born at Cesena on Dec 27 1717 After taking the degree of doctor of laws he went to Ferrara and became the private secretary of Cardinal Ruffo in whose bishopric of Ostia and Velletri he held the post of *uditore* until 1753 His skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV who appointed him one of his secretaries and canon of St Peters In 1758 he was raised to the prelature and in 1766 to the treasurership of the apostolic chamber by Clement XIII and in 1775 he became cardinal priest of San Olofrio In the four months conclave which followed the death of Clement XIV Spain France and Portugal at length dropped their objection to Braschi and he was elected to the vacant see on Feb 15 1775

Pius had received the support of the ministers of the Crowns and the anti Jesuit party upon a tacit understanding that he would continue the action of Clement by whose brief *Dominus ac redemptor* (1775) the dissolution of the Society of Jesus had been pronounced On the other hand the *zelanti* who believed him secretly inclined towards Jesuitism expected from him some reparation for the alleged wrongs of the previous reign The half measures adopted by Pius gave little satisfaction to either party It is perhaps largely due to him that the order was able to escape shipwreck in White Russia and Silesia in 1792 he considered its re establishment as a bulwark against revolutionary ideas

The authority of the papacy was threatened in Austria by the social and ecclesiastical reforms undertaken by Joseph II and in the hope of staying them Pius adopted the exceptional course of visiting Vienna in person His mission proved a fiasco he was however able a few years later to curb those German archbishops who in 1786 at the Congress at Ems had shown a tendency towards independence Difficulties also arose in Naples and in Tuscany At the outbreak of the French Revolution Pius saw the old Gallican Church suppressed the pontifical and ecclesiastical possessions in France confiscated and an effigy of him self burnt by the populace at the Palais Royal The murder of the republican agent Hugo Basseville in the streets of Rome (January 1793) gave new ground of offence the papal court was charged with complicity by the French Convention and Pius threw in his lot with the league against France In 1796 Napoleon invaded Italy defeated the papal troops and occupied Ancona and Loreto Pius sued for peace which was granted at Tolentino on Feb 19 1797 but on Dec 28 of that year in a riot created by some Italian and French revolutionists General Duphot of the French embassy was killed and a new pretext furnished for invasion General Berthier marched to Rome entered it unopposed on Feb 13 1798 and proclaiming a republic demanded of the pope the renunciation of his temporal authority Upon his refusal he was taken prisoner and on Feb 20 was escorted from the Vatican to Siena and thence to the Certosa near Florence The French declaration of war against Tuscany led to his removal by way of Parma Piacenza Turin and Grenoble to the citadel of Valence where he died six weeks later on Aug 29 1799 Pius VII succeeded him

**PIUS VII** (Luigi Barnaba Chiaramonti) pope from 1800 to 1823 the son of Count Scipione Chiaramonti and the deeply religious Countess Ghini was born at Cesena on Aug 14 1740 (not 1742) He entered the Benedictine monastery of St Mary at Cesena and held various teaching appointments in the colleges of his order at Parma and at Rome He was created an abbot bishop of Tivoli in 1782 and raised him to the cardinalate and the see of Imola in 1785 He became pope on March 14 1800

His attention was at once directed to the ecclesiastical anarchy of France, and he negotiated the celebrated concordat of 1801

*See CONCORDAT*) The importance of this agreement was how ever considerably ened by the article organique appended to it by the French government on April 5 1803. In 1804 Napoleon opened negotiations to secure at the pope's hand his formal consecration as emperor. After some hesitation he was induced to perform the ceremony at Notre Dame and on the day of his visit to Paris for four months but in return for his favours he was able to obtain from Napoleon merely one or two minor concessions. Napoleon soon began to disregard the Italian concordat of 1803 and himself decreed the dissolution of the marriage of his brother Jerome with Miss Patterson of Baltimore. The irritation between France and the Vatican increased so rapidly that on Feb. 1808 Rome was occupied by General Miollis a month later the provinces of Ancona Macer a Fermo and Urbino were united to the kingdom of Italy and diplomatic relations between Napoleon and Rome were broken off finally by a decree issued from Schonbrunn on May 1, 1809 the emperor united the Papal States to France. Pius retaliated by a bull communicating the invaders and to prevent insurrection Miollis—either on his own responsibility as Napoleon afterwards asserted or by order of the latter—employed General Radet to take possession of the pope's person. On July 3 Pius was made prisoner he was taken to Grenoble and then to Savona where he steadfastly refused canonical institution to the bishops nominated by Napoleon. In 1810 the aged and sick pontiff was removed to Fontainebleau where he was lodged in a suite of regal magnificence to await the return of the emperor from Moscow. When Napoleon arrived he entered into personal negotiations with the pope who on Jan. 25 1813 assented to a concordat so degrading that his conscience found no relief until on the advice of the cardinal Pacca and Consalvi he abrogated it (March 24) and on the 9th of May he defied the emperor by declaring invalid all the official acts of the new French bishops. Napoleon sent him back to Savona for safe keeping but the course of events in 1814 forced him to liberate the pope and give back the States of the Church. On the 19th of March Pius left Savona and was received with rejoicing at Rome on May 4. Reaction set in at Rome the Jesuits were restored the French legislation much of which was of great social value was repealed the Index and the Inquisition were revived. On his return from the congress of Vienna Consalvi conducted a more enlightened and highly centralized administration based largely on the famous *Motu proprio* of 1816 nevertheless the finances were in a desperate condition. Discontent centred perhaps in the *Carbonari* a Liberal secret society condemned by the pope in 1821. Consalvi negotiated a series of valuable concordats with all the Roman Catholic powers save Austria. In the latter years of Pius's life royalty often came to Rome the pope was very gracious to exiled kings and showed notable magnanimity toward the family of Napoleon. He attracted many artists to the city including the greatest sculptors of the time one of whom the Protestant Thorwaldsen prepared the tomb in which repose the remains of the gentle and courageous pontiff who passed into rest on Aug. 30 1823. His successor was Leo XII.

**PIUS VIII** (Francesco Xaviero Castiglioni) pope from 1829 to 1830 was born at Cingoli on Nov. 20 1761. He studied canon law at Rome became vicar general at Anagni and later at Fano in 1800 was appointed bishop of Montalto and in 1816 of Cesena.

In 1818 he was made cardinal bishop of Frascati also grand penitentiary and later he became prefect of the Congregation of the Index. In the conclave which followed the death of Leo XII Castiglioni the cardinal of France was elected pope on March 1 1829. He brought the system of espionage employed by his predecessor and published an encyclical condemning Bible societies and ecclesiastical innovation. He exhibited a pacific spirit in dealing with the problem of mixed marriage in Germany. He died on Dec. 30 1830. His successor was Gregory XVI.

*See* Zopffel and Benrath Pius VIII in Herzog Hauck *Realencyklopadie* xv 458 seq. (Leipzig 1904) with bibliography. F. Nielsen *A History of the Popes in the 19th Century* ii 1-50 (1906). P. B. Gam *Serie episcoporum ecclesiarum holmarum* (Regensburg 1831).

**PIUS IX** (Giovanni Maria Masini Ferretti) pope from 1846 to 1878 was born on May 13 1797 at Sinigaglia the fourth son of Count Jerome and Countess Catherine Vollazi. The family of Mastai was of ancient descent and the title of count came to it in the 17th century while later the elder branch allied by marriage with the Ferretti family took that name in addition. He spent some time at the College of Piarists in Volterra and prepared to enter the pontifical guard as an officer but was refused on the ground that he suffered from epilepsy. The malady however was surmounted and in 1819 he was ordained priest. After ministering for some time in his native town he accompanied Cardinal Muzza to Chile (1835). On his return he was entrusted by Leo XII with the direction of the Roman hospital of San Michele. In 1830 he received the archbishopric of Spoleto in 1833 the bishopric of Imola and in 1840 Gregory XVI created him a cardinal with the title Santi Pietro e Marcellino.

On the death of Gregory XVI (June 1 1846) the College of Cardinals met in conclave on June 14 and on June 16 Mastai Ferretti obtained the requisite two thirds majority and ascended the papal chair under the title of Pius IX. In his various capacities he had gained much popularity he had shown himself to be of a kindly disposition and a zealous churchman and his reputation for piety and tact stood high he possessed too a winning personality and a handsome presence.

**Papal Reforms**—The reign of Pius IX began at an extremely critical time. The problem of the government of the Papal States transmitted to him by his predecessor stood in urgent need of solution for the conditions were intolerable. Dissatisfaction found vent in revolts which could only be quelled by the intervention of foreign powers and the ferment in the dominions of the Church was accentuated by the revolutionary disturbances throughout ascendant in all the states of Europe. The proclamation of a general political amnesty made an excellent impression and Pius at once instituted preparations for a reform of the administration the judicature and the financial system. The regulations affecting the censorship were mitigated and a breath of political liberalism vitalized the whole government. Pius at once acquired the reputation of a reforming pope. But two demands were urged with ever increasing energy—a share in the government and a national Italian policy. The problem of popular representation was one of peculiar difficulty in the Papal States. It was not simply a question of adjusting the claims of monarch and subject it was necessary to oust the clergy—who till then had held all the more important offices—from their dominant position or at least to limit their privileges. That the clerical character of the administration could not be indefinitely retained was plain to any clear thinking statesman for since the restoration of the Papal State in 1814 the pernicious effects of this confusion of the spiritual and the secular power could no longer be denied. But Pius IX lacked the courage and perspicacity to draw the inevitable conclusions from these premises and the higher clergy at Rome were naturally opposed to any change which would deprive them of power and privileges. In the course of the year 1847 the pope by a series of decrees gave a reorganized municipal council to Rome and instituted a state council and a responsible ministry but these reforms were hedged in with reservations which made them unacceptable to the people. In March 1848 the pope promulgated a constitution with a parliament consisting of two chambers.

**Revolution of 1848**—The utility of this constitution was

never tested for the demand for an extension of popular rights was now eclipsed by a still more passionate aspiration towards the national unity of Italy. This nationalist movement at once took head against Austria. On March 18 the revolution broke out in Milan and King Albert of Sardinia undertook the conduct of the war against the emperor. The populace was swept by a whirlwind of enthusiasm the Austrian embassy was mobbed the imperial arms surmounting the main gate of the palace were torn down and great troops of volunteers clamoured to be led against Austria. Pius seemed after his proclamation of March 30 on the point of conferring his blessing upon the war against Austria. But on April 29 in his allocution to the cardinals he proclaimed the papal neutrality and the storm broke. Mamiani, Fabbri and Rossi in successive ministries sought to restore order. On Nov. 15 Rossi was assassinated as he was about to open the session of the chambers. The pope then assented to the formation of a radically democratic ministry under Caletti. The Swiss who composed the papal guard were disbanded and the protection of the pontiff was transferred to the civil militia. In other words Pius IX. was a prisoner. On Nov. 24 he fled with the aid of the French and Bavarian ambassadors—the duc d'Harcourt and Count Spaur—to Gaeta in the kingdom of Naples. On Feb. 9 1849 the constituent assembly decreed by 14 votes to 23 the erection of a Roman republic. Pius answered by a protest dated Feb. 14. He had already appealed to the European Powers for assistance for the intervention of France and Austria. *see ITALY*. On July 14 Oudinot proclaimed the restoration of the pontifical dominion and three days later Pius IX. issued a manifesto entrusting the government to a commission appointed by himself.

**Loss of the Temporal Power**—On April 1 1850 Pius returned to Rome supported by foreign arms embittered and hostile henceforward to every form of political liberalism or national sentiment. In Gaeta he had mentally cut himself loose from all ideas of progress and had thrown himself into the arms of the Jesuits. His subsequent policy was stamped by reaction. Whether it might have been possible to avoid the catastrophe of 1850 in which the remnant of the Papal States was lost is a difficult question. But undoubtedly the policy which Pius now inaugurated of restoring the old pre-revolutionary conditions sealed the fate of the temporal dominion of the papacy. He made no attempt to regain the estranged affections of the populace and took no measures to liberate himself and his subjects from the incubus of the last few years. The system of precautionary arrest as it was termed rendered it possible for any man to be thrown into prison without trial and without verdict simply on the ground that he lay under suspicion of plotting against the Government. The priests who usurped the judicial function displayed such cruelty on several occasions that officers of the Austrian army were compelled to record a protest. The consequence of these methods was that every victim—innocent or guilty—ranked as a martyr in the estimation of his fellow citizens. Brigandage revived corruption was rampant and the financial administration under Cardinal Antonelli (*qv*) was disastrous.

The mismanagement which obtained in the papal dominions could not escape the observation of the other powers. As early as the Congress of Paris in 1856 the English ambassador Lord Clarendon had directed an annihilating criticism against the government of the pontiff and a convincing proof of the justice of his verdict was given by Pius himself in his treatment of the famous Mortara case (*see MORTARA EDGAR*) which gave rise to diplomatic representations from France and England. The sequel to this mode of government was that the growing embitterment of the subjects of the Church came to be sympathized with outside the bounds of Italy and the question whether the secular authority of the papacy could be allowed to continue became a much debated problem. The continued existence of the Papal States as such depended in fact on the maintenance of the understanding between the two powers protecting the papal state—France and Austria.

But Napoleon came to an agreement with Cavour against Austria and one of the results of the war of 1859 was that the pope forfeited two-thirds of his dominions. After the war of

1866 (*see ITALY History*) the States of the Church formed the last remaining obstacle to complete national unity. The ruins of the fall of the French empire in 1800 produced an electrical effect in Italy. The French troops had evacuated Rome in 1869 and the Italian parliament now called on the king to occupy Rome. On Sept. 8 Victor Emmanuel crossed the borders and on Sept. 10 the green white and red of the tricolour floated over the Capitol. The protests of Pius IX. remained unheeded and his attempts to secure another foreign intervention met with no success. On Oct. 3 Victor Emmanuel instituted a *plebiscite* in Rome and the positions of the Church to decide the question of annexation. The result of the suffrage was that 153,681 votes were given in favour of union with Italy and 1,507 against the proposed incorporation—that is to say only the direct dependants of the Vatican were opposed to the change. The papal state was now merged in the kingdom of Italy which proceeded to define its diplomatic relations with the Holy See by the law of May 13 1871 (*see ITALY History*).

**Ultramontanism**—In his capacity as head of the Church Pius IX. adhered to the principles of the Ultramontane party and contributed materially to the victory of that cause. The political reaction which followed the revolutionary era in most quarters of Europe offered a favourite soil for his efforts and in several countries he found it possible to regulate the relations between Church and state from the standpoint of the curia. In 1851 he concluded a concordat with Queen Isabella II. of Spain proclaiming Roman Catholicism the sole religion of the Spanish people to the exclusion of every other creed (art. 1) and we find the same provision in another concordat with the South American republic of Ecuador (1861). A third concordat negotiated with the emperor Francis Joseph I. of Austria (1855) entrusted the supervision of schools and the censorship of literature to the clergy recognized the canon law and repealed all secular legislation conflicting with it. France came into line with the wishes of the pope in every respect as Napoleon needed clerical support in his political designs. Even in Germany he found no resistance on the contrary he was able to secure advantageous compacts from individual states (Hesse 1854 Württemberg 1857).

Among the most important acts of Pius IX. must be counted his proclamation of the dogma of the Immaculate Conception of the Virgin Mary by the bull *Ineffabilis Deus* on Dec. 8 1854. In this bull the preservation of Mary from every stain of hereditary sin in the first moment of her conception was declared to be a divinely revealed truth which consequently demanded universal acceptance (*see IMMACULATE CONCEPTION*). By this means a view which till then had been no more than a pious belief was elevated into a dogma to be held *de fide* though grave doubts on the subject had always been entertained even in the midst of the Church itself. For the inner life of that Church this solution of the controversy was of great significance and created a desire for further dogmatic decisions on the Virgin Mary—her resurrection and ascension.

As reigning sovereign of the Papal States Pius IX. had passed through a liberal period as head of the Church he had never been liable to attacks of liberalism. Nevertheless his return from exile left its mark on his spiritual administration. For from this period onwards he set his face against the influence of modernism on ecclesiastical life showed his displeasure at and distrust of the scientific theology and philosophy which marked a moderate advance (Gunther, Frohschammer and Dollinger) and entrenched in the stronghold of mediaeval ideals combated the transformations of the new order of society and the changes in the relationship between Church and state which obtained in most countries of Europe since the French Revolution. After long and careful consultation the adverse criticisms which he had expressed on various occasions were published on Dec. 8 1864 together with the encyclical *Quanta cura* under the title *Syllabus errorum praeceptis nostrae aetatis errores* (*see SYLLABUS*). In this Pius claimed for the Church the control of all culture and all science, and of the whole educational system. He rejected the liberty of faith conscience and worship enjoyed by other creeds; and

bade an easy farewell to the idea of one man. He claimed the complete independence of the Church from the control upheld the necessity of a canon law to the emperor and of the Roman See and finally in 1871 he declared that the pontiff neither can be nor ought to be reformed. All progress liberalism and modern civilization.

The publication of his syllabus created a profound impression for it declared war on modern society and omitted the papacy to the principle of Ultramontanism (q.v.). But as any attempt to translate its precepts into practice would entail a disastrous conflict with the existing regime established by law Roman Catholic circles have frequently shown a tendency to belittle the significance of the manifesto and to deny that its rules are absolutely binding. But the well-meant explanations however comprehensible are refuted by the unequivocal pronouncements of Pius IX, Leo XIII and many recognized ecclesiastical authorities—e.g. Cardinal Manning, Archbishop of Westminster who described the syllabus as an emanation from the highest doctrinal authority in the Church.

**Infallibility**—The zenith of Pius's pontificate was attained on July 18, 1870 when the Vatican council proclaimed the infallibility of the pope and the universality of his episcopate thus elevating him to a pinnacle which none of his predecessors had reached and at the same time fulfilling his dearest wish. That personally he laid great stress on the acceptance of the dogma was a fact which he did not attempt to conceal during the long preliminary deliberations of the council and his attitude was a not inconsiderable factor in determining its final resolutions. But the loss of the Papal States immediately afterwards was a blow from which he never recovered. Whenever he brought himself to speak of the subject—and it was not rarely—he repeated his protest in the bitterest terms and to the end of his days refused to be reconciled with the sacrilegious king of Italy. When in Germany the situation created by the Vatican council led to the outbreak of the *Kulturkampf* Pius IX failed to display the tact peculiar to his successor. For in the encyclical *Quod nunquam* (Feb. 5, 1875) he took the rash step of declaring invalid the Prussian laws regulating the relationship between Church and state—the only result being that the feud was still further embittered.

In these later years the dark days of his captivity were amply compensated by the proofs of reverence displayed by Roman Catholic Christianity which accorded him magnificent ovations as his period of jubilee began to fall due. The twenty-fifth anniversary of his pontificate was celebrated with great splendour on June 16, 1871 for he was the first pope who had thus reached the traditional years of Peter. In 1872 his 80th birthday gave occasion for new demonstrations and 1875 was a so-called year of jubilee. Finally in 1877 the fifty years of his priesthood were completed an event which brought him innumerable expressions of loyalty and led to a great manifestation of devotion to the Holy See from all the Roman Catholic world. He will be remembered as the pope who re-established the hierarchy in England. On Feb. 7, 1878 Pius IX died. His successor was Leo XIII (C. M. X.).

**PIUS X** (Giuseppe Sarto) pope from Aug. 4, 1903 to Aug. 20, 1914 was born of humble parents on June 2, 1835 at Riese in the province of Treviso, Italy and studied at the episcopal seminaries of Treviso and Padua being ordained priest in 1858. For 17 years he acted as parish priest at various places in Venetia

until his appointment in 1875 a canon of the cathedral and superior of the seminary at Treviso. In 1880 he received the bishopric of Tivoli but accepted that of Mantua in 1884 at the command of Leo XIII. On June 1, 1893, he was created a cardinal and the day after was nominated patriarch of Venice with full powers of jurisdiction and directs to act in harmony with the Italian Government and his very popular. He succeeded Leo XIII in his election to the papal chair on Aug. 4, 1903.

During his pontificate in the doctrine of the faith his condemnation of the 65 propositions of Modernism in 1907 will rank as a parallel to the condemnation of the 68 propositions of Molinism by Innocent XI in 1679 or the 10 propositions of Jansenism condemned by Clement XI in 1713.

Reform of the first importance were undertaken—the codification of canon law, the protection of the liberty of the conclave by the abolition of the *exclusa*, the simplification and security of the conditions of marriage by the *no temere* legislation, the restoration of the Rota as the supreme court of appeal, the regulation of the triennial or quinquennial visits of bishops to Rome, the legislation as to church music and the decree as to first communion and the encouragement of international eucharistic congresses, the reform of the Roman breviary, the founding of the biblical institute for the work of Scriptural research, the regulation of studies in the seminaries, the creation of the commission for the great work of editing the true text of the Vulgate, the reconstruction of the official machinery of the Roman curia, the transfer of the English-speaking countries from the propaganda or missionary regime to the normal government of the Church. To these may be added in the domain of discipline the unflinching vindication by Pius X of the Church's right to depose delinquent bishops carried out even at the cost of rupture of diplomatic relations with France, an apostolic visitation rigorously carried out through the dioceses of Italy resulting in four bishops being made to resign on account of neglect or inefficiency, a further regulation by which no one can be proposed for a bishopric unless his promotion receives the visa of the Holy Office which means that his past life has been free from ecclesiastical censure or reproach.

The well-known personal characteristics of Pius X were his piety, charity, deep humility, simplicity, pastoral zeal combined with great charm of manner to all who approached him. For war he had nothing but horror and it was the shock of the outbreak of the World War that hastened his death which took place in Rome on Aug. 20, 1914. It is said that one of his last acts was to refuse the request of the Austrian emperor to bless his cause saying: "I do not bless war. I bless peace."

**PIUS XI** (1857– ) pope since 1919 was born on May 31, 1857 at Desio, a small town north of Monza in the environs of Milan on the road to Como and was named Ambrose Damien Achille. His father was Francesco Ratti, the manager of one of the great silk factories of Desio and partner in the firm of Gadda. Achille was educated at the seminaries of San Pietro Martire and of Monza and at the college of St. Charles at Milan where he graduated. Feeling that he was called to the priesthood he studied for two years in the greater seminary. His life at this time was profoundly influenced by his spending his vacation months with his uncle Don Rodolpho, the venerable and exemplary parish priest and provost of Asso, a village in the promontory of the Bellagio. From his windows he could see Lake Como and the Alps of which later on he was so strongly to feel the lure. It was also here that he came under the personal notice of the archbishop of Milan, Mgr. Nazario di Calebiana, who was staying as the guest of Count de Herra and was a frequent visitor at his uncle's presbytery. The archbishop was much struck by the future pope's earnestness and maturity of judgment and was wont to call him his "young old man." Ever afterwards he took a deep interest in his career. He sent him to the college of St. Martin and then to Rome to study at the Lombard college and attend the lectures at the Gregorian university. Here Achille Ratti took with distinction the degrees of doctor of philosophy, of theology and canon law. He was ordained priest on Dec. 20, 1879.

At the Lombard college his fellow student and closest friend

hall really end in *hale* nook or corner of land. The proximity of some similar sounding name may lead to its ultimate substitution as when *Combe in Ternhead* replaces *Comb in Tern* because the place stands on a headland at the mouth of the *Tern*.

**Folk Etymology**—When we come across a name which in itself conveys no meaning we are apt to turn it into something which conveys some sort of meaning however inapposite. Thus all the places once called *Finehede* have now become *Finehale* or *Finefield* since we are no longer aware what a hide of land is. *Highenovre* (lit. high bank) become *High* and *Oer*. Folk etymology has led to the formation of a series of 'hot' place names commonly spoken of as back formations. *Cambridge* is assumed to be the bridge over the Cam and the river is hence forward so called though in reality *Cambridge* is an Anglo-Norman corruption of an earlier *Grantabryc*, and the correct name of the river is *Granta*. This process is specially common with river names. The Sussex *Arun* and *Rother* are back formations from *Arundel* and *Rotherfield* while the *Idur* is a back formation from the false identification of *Portus Adurni* with Shoreham. The old names for the rivers in this case *Tarrant* *Limen* *Bramber* were early lost and new names had to be found.

Early forms of certain names may be recorded by early geographers, historians or chroniclers but for most we have to turn elsewhere to national surveys such as *Domesday Book* or the Danish Landbook of King Valdemar to ancient charters which often give not only the name of the land granted but also the names of the land marks on its boundaries, royal and episcopal documents of every kind and in later days survey extents, terriers, maps. Here fresh difficulties arise. We find a large number of faulty and fantastic spellings as when *Knighton* (OE *cnihstun*) commonly appears in *Domesday* as *Chenstetone* or *Gilling* (OE *Gillingas*) is disguised as *Gwyllingues*. Such forms if they appeared repeatedly in official documents might actually be recognized as the correct names even locally. Thus the *Cren* of *Cirencester* is the Norman-French spelling for the native English *Churn*, the river on which that town stands, and *Durham* is the result of the Normans' attempt to pronounce *Dunholm* in which the sound combinations *nh* and *lm* proved too difficult for him.

**Interpretation**—In the interpretation of early forms we have first words descriptive of the actual topography and secondly personal names belonging to those who have been owners or occupiers of the site. Most of the descriptive words can readily be recognized but a goodly number furnish difficulties. Our knowledge of the vocabulary of our forefathers is derived chiefly from works of religious or homiletic character and there are extensive gaps in our knowledge of their secular vocabulary especially in its earliest stages. These lost words may be found in place names. Thus in *Herne* (Bedf.) and *Harome* (Yorks) we have an otherwise unknown OE *har* a stony place, heap, hill, found in various cognate languages. So also a word in common use in early days may have passed completely out of use in our language and still survive in place names. OE *hearg* heathen grove only survives in such place names as *Harrow*, *Harrowden* and *Arrow Hill*. And similar difficulties arise with regard to the personal names found in place names. Often when a personal name has been assumed the very name itself turns up later in some newly discovered document. Thus a personal name *Bhucc* with a diminutive *Bhucgel* was assumed to explain *Blucking* and then later the name was found in a 13th century cartulary.

In most countries we have to deal not with one people or language alone but with successive settlements by peoples using different languages. If the new race is only a powerful minority as for example the Normans in England or the English in Ireland its influence on place names may be very small. In the case of the Romans in Celtic Britain it was almost negligible. If the invasion or settlement was a mass one there may be a very extensive renaming of the places as was the case with the English in most parts of England, the Vikings in certain parts of the Danelaw and in Normandy and the Celtic refugees who settled in Brittany. In England the dominant race and speech since the beginning of the 6th century has been English and, ex-

cept in Cornwall, Monmouthshire and Herefordshire the nomenclature of the counties of England is predominantly English or Scandinavian. The only exception to this general statement is to be found in a good number of the names of natural features such as rivers and roundains. Here and in other countries also the old names were usually kept. The rivers ran through wide tracts of country and were not the property of any single settler while the mountings had no attractions for settlers in search of good pasture or arable land. Thus it is that *Wear*, *Tyne*, *Avon*, *Cheviot*, *Eildon*, *Wiltren*, *Mendip* are Celtic names though English ones are not entirely wanting as for example *Blyth*, *Loud*, *Clent*. Many river and hill names cannot be explained even upon a Celtic basis and may have been taken over by the Celts from still earlier peoples. We must also note that some names which now look convincingly English may really be folk-etymological perversions of earlier Celtic names. The Celtic name has in a few cases survived to prove it as in the case of OE in *Eoforwic*, *Searoburh*, our *York* and *Sahsbury* which mean in Old English 'boar dwell' and 'trickery fort' respectively but are really Anglicisings of the old Romano-Celtic names *Eburacum* and *Sorbiodunum*. How many similar cases there may be in which the evidence for it has not chanced to survive it is impossible to say.

The Romans seldom renamed the British towns and beyond one or two somewhat doubtful examples such as *Speen* and *Chester* (earlier *Lega caester*) and *Lincoln* from the Latin *spinae* (walls) *legionis* and *lindum coloma* they left little to be handed on to the English. The latter had picked up a certain number of Latin words both in their old Continental homes and in England through the channels of war and trade and Christianity such as *castra* (wall) *strata* *monasterium*. These became *caester*, *Strat* and *mynster* in their own language and have given rise to groups of names in *chester*, *cester*, *caster* in *Street*, *Stret*, *Strat*, *Streat* and in *munster*. The first of these elements is very commonly found in the names of the old Romano-British fortified towns but it should be noted that the first element in such names (e.g. *Gloucester*, *Cirencester*, *Wroxeter*, *Exeter*) is Celtic and not Roman, the old names being *Glevum*, *Cornunum*, *Uricornum* and *Isca*.

The English Conquest involved widespread renaming of the countryside. The comparative frequency of place names in *ing* and *ingham* in the eastern and south-eastern counties and their comparative rarity elsewhere suggests the importance of the great leader and his followers in the early stages of the invasion. For in OE the suffix *ing(as)* was added to a personal name to denote that man and his family followers etc. Thus *Basing* denotes the followers of *Basa* and *Whittingham* is the home of the followers of *Hwita*. The elements *ham* and *stede* site place later *ste(a)d* were freely used in the early days of the invasion. The suffix *ton*, from OE *tun* enclosure, becomes relatively much more frequent as we travel westwards to the districts latest conquered and this suffix remained a living one till long after the Norman Conquest. *Worth*, *worthy* and *wardine* all denote small enclosures but the first soon ceased to be a living suffix. *Port* was used for a town (a loan word from Lat. *porta*) and *burh* (dat. sing. *byrig*) is the source of many names in *bury* and a few in *borough*, *burgh*. It denotes a fortified place of whatever age and has none of the constitutional associations of the common word *borough*. Large areas of land were still covered with forest as these were brought under cultivation names in *ley* and *field* arose from the OE words *leah* clearing in woodland and *feld* open country. Land dedicated to the service of religion was often called *stow* hence *Halstow* holy place, *Bridstow* St. Bride's land corresponding to the Welsh *Llan san Bregit*. Many other elements of a purely topographical character are found in place names. Here and in other countries we find early peoples very sensitive to slight differences of terrain and a place might be called a *cliff* e.g. *Egglescliffe* or *hangra* (i.e. hanging wood) as in *Shelfanger* where we should only note a slight slope. The personal names found in these place names especially in eastern and south-eastern England, are often of an exceedingly archaic type, suggesting that soon after the settlement there were rapid changes in the nomenclature among our forefathers.

The Scandinavian settlement of certain districts of England

The main sphere of Norman French influence on place names has already been indicated viz its importance in changing the spelling and pronunciation of many of the older names. Such influence was specially common in the neighbourhood of the great castles and monasteries. They themselves often bore French, or

(A M)

**Mode of Formation**—Before each menstrual period during the child bearing age of a woman the mucous membrane of the uterus hypertrophies and at the period is cast off but if a fertilized ovum reaches the uterus the casting off is postponed until the birth of the child. From the fact that the thickened mucous membrane lining the interior of the uterus is cast off sooner or later it is spoken of as the decidua. The fertilized ovum on reaching the uterus embeds itself in the already prepared decidua and as it enlarges, there is one part of the decidua lying between it and the uterine wall (decidua serotina or "basalis"), one part stretched over the surface of the enlarging ovum (decidua reflexa or "capsularis") and one part lining the rest of the uterus (decidua vera") (see fig. 1). It is the decidua

basalis which is specially concerned in formation of the placenta. That part which is nearest the ovum is called the stratum compactum but farther away the uterine glands dilate and give a spongy appearance to the mucous membrane (stratum spongiosum). Processes from the surface of the ovum pierce the stratum compactum and push their way into the enlarged maternal blood sinuses these are the chorionic villi. Later

FIG 1—DIAGRAM REPRESENTING A VERY YOUNG HUMAN OVUM ALMOST IMMEDIATELY AFTER ITS ENTRANCE INTO THE DECIDUA THE PLACE OF ENTRANCE STILL BEING COVERED WITH A PLUG OF FIBRIN

the allantoic or abdominal stalk grows from the mesoderm of the hind end of the embryo into the chorionic villi which enter the decidua basalis and in this blood vessels push their way into the maternal blood sinuses. Eventually the original walls of these sinuses and the false amnion disappear and nothing separates the maternal from the foetal blood except the delicate walls of the foetal vessels covered by undifferentiated nucleated tissue (*syncytium*) derived from the chorionic epithelium so that the embryo is able to take its supply of oxygen and materials for growth from the blood of its mother and to give up carbonic acid and excretory matters. It is the gradual enlargement of the chorionic villi in the decidua basalis together with the intervillous maternal blood sinuses that forms the placenta. The decidua capsularis and vera become pressed together as the embryo enlarges and atrophy. The allantoic stalk elongates enormously and in its later stages contains two arteries (umbilical) and one vein embedded in loose connective tissue known as Wharton's jelly. At first the stalk of the yolk sac is quite distinct from this but later the two structures become bound together (see fig 2) as the umbilical cord. A distinction must be made between the allantoic stalk and the allantois the latter is an endodermal outgrowth from the hind end of the mesoderm or primitive alimentary canal which in the human subject only reaches a little way toward the placenta. The allantoic stalk is the mass of mesoderm containing blood vessels which is pushed in front of the allantois and as has been shown reaches and blends with the decidua basalis to form the placenta.

For further details see Quain's *Anatomy* vol 1 (London 1908) and for literature O Hertwig's *Handbuch der Entwicklungslehre* (Jena)

**Comparative Anatomy**—If the placenta is to be regarded as a close union between the vascular system of the parent and embryo the condition may be found scattered throughout the phylum of the Chordata. In so lowly a member as *Salpa* a placenta is formed and the embryo is nourished within the body of its parent. In some of the viviparous sharks e.g. the blue shark (*Carcharias*) the yolk sac has ridges which fit into grooves in the wall of the oviduct and allow interchange between maternal and foetal blood. This is an example of an umbilical placenta. In the viviparous blennies (*Zoarces viviparus*) among the teleostean fishes 200 or 300 young are nourished in the hollow ovary which develops villi secreting nutritive material.

The mammals are divided into Placentalia and Aplacentalia. In the latter group to which the monotremes and most marsupials belong the ova have a great deal of yolk and the young born in

a very immature condition finish their development in their mother's pouch but although these mammals have no allantoic placenta there is an intimate connection between the walls of the yolk sac and the uterine mucous membrane and so an umbilical placenta exists. The name Aplacentalia therefore only means that they have no allantoic placenta. Among the Placentalia the umbilical and allantoic placentae sometimes coexist for some time as in the hedgehog, bandicoot and mouse.

In the Carnivora elephant, procavia (Hyrax) and aardvark (*Orctopus*) there is a zonary placenta which forms a girdle round the embryo. In sloths and lemurs the placenta is dome-shaped while in rodents, insectivores and bats it is a ventral disk or closely applied pair of disks thus differing from the dorsal disk of the anteater, armadillo and higher Primates which is known as a metadiscoidal placenta. Thus the form of the placenta is not an altogether trustworthy indication of the systematic position of its owner. In the diffuse and cotyledonous placentae the villi do not penetrate very deeply into the decidua and at

**PLACERS**, the common name given to the alluvial deposits in which gold frequently occurs. They consist of sand and gravel deposited by existing or former streams of water carrying de

tritus of gold bearing rock. Other metals as tin are similarly deposited. The gold of the placers consists of small rounded nuggets. The placer of an ancient stream may be deep lying because covered since its formation with other deposits or even alluvium. (See *GOLD Mining and Metallurgy*)

**PLAGIARISM**, an appropriation or copying from the work of another in literature or art and the passing off of the same as original. The Latin *plagiarius* meant a kidnapper, teacher or abductor of a slave or child though it is also used in the modern sense by Martial (I, 59). (See *COPYRIGHT*)

**PLAGIOCLASE**, an important group of rock forming minerals constituting an isomorphous series between albite feldspar and anorthite feldspar. The intermediate members are soda lime feldspar which in their crystallographical optical and other physical properties vary progressively between the two extreme albite (Ab)  $\text{NaAlSi}_3\text{O}_8$  and anorthite (An)  $\text{CaAl}_2\text{Si}_2\text{O}_8$ . The name plagioclase is derived from the Greek *πλαγιος* oblique and *κλαυν* to break in allusion to the oblique angle between the cleavages. Names are applied to members of the plagioclase group falling between certain arbitrary composition limits those now commonly adopted being albite (Ab<sub>100</sub>-Ab) oligoclase (Ab - Ab) andesine (Ab - Ab<sub>50</sub>) labradorite (Ab<sub>50</sub>-Ab) bytownite (Ab - Ab) anorthite (Ab - An<sub>100</sub>). The pure end members are practically unknown in nature. All the plagioclases crystallize in the triclinic system and as members of an isomorphous series show closely similar crystallographic constants. They possess a perfect cleavage parallel to the basal pinacoid (001) and a less pronounced cleavage parallel to the pinacoid (010) the angle between the two cleavages varying progressively from 86° 4' in albite to 85° 50' in anorthite. The molecular volume are closely similar (Ab 100.1) (An 101.5). The habit of well formed crystals is usually tabular on the plane 010 sometimes flattened parallel to 001 or as in microlitic plagioclases of volcanic rocks elongated in the direction of the edge 001 010. Twinning is a very important character of the plagioclases being almost invariably present and affording a ready means of distinguishing them from other feldspars. The chief twin laws are the Carlsbad albite and pericline the latter two being commonly polysynthetic give rise to numerous thin lamellae which are the cause of the fine striations seen on cleavage planes and of the banded character visible in thin sections of the minerals examined in polarized light.

With the exception of the sodic end member (albite) which owing to the high viscosity of its melts is with difficulty crystallized the plagioclases are readily prepared from dry melts of the component oxides. They show a continuous melting curve the intermediate members exhibiting a melting interval. The temperatures of beginning of melting (solidus) have been determined in the laboratory for compositions ranging from pure An to Ab<sub>100</sub> and of completion of melting (liquidus) for a range An to Ab<sub>100</sub>. These data are shown below.

Composition	Temperature of beginning of melting (solidus)	Temperature of completion of melting (liquidus)
Albite (Ab <sub>100</sub> An)	1100 C	—
Oligoclase (Ab <sub>85</sub> An)	1175 C	1362 C
Andesine (Ab An)	1205 C	1394 C
Andesine Labradorite (Ab An)	1287 C	1450 C
Labradorite (Ab An)	1372 C	1490 C
Bytownite (Ab An)	1465 C	1521 C
Anorthite (An <sub>100</sub> )	1550 C	1550 C

The density and mean refractive index of the plagioclase feldspars vary progressively the extremes being albite  $D = 2.605$   $\mu = 1.530$  anorthite  $D = 2.765$   $\mu = 1.587$ .

Since the plagioclases are of great importance in petrology much detailed study of their optical properties has been undertaken, so that it is now possible to determine by simple examination of thin slices of these minerals the exact chemical composition and crystallographic orientation of the selected section. For this purpose the chief determinations are the refractive indices, and the optical extinctions of oriented sections principally on

cleavage plates (001 and 010) sections cut perpendicular to the optic axes and biotites and especially those perpendicular to the plane of albite twinning (010) in multiple twinned crystals. Other optical determinations are available for discriminating between members of the group.

**BIOTITE**—For a detailed summary of the optical character and their employment in the recognition of the quantitative composition of the mica the reader should be consulted H. Rosenbach *Mikroskopische Petrographie der Mineralien und Gesteine* Band 1 Zweite Hälfte 3. Auflage revised by O. Muehlberg 1919 L. Duparc and M. Reinhard *La Détermination des Plagioclases* (Mem. Soc. Phys. Hist. Nat. Geneve 1914 fasc. 1) A. N. Winchell *Element of Opt. of Minerals* (1919 pp. 41). For a recent preliminary X-ray study of the plagioclase solid solution reference may also be made to E. Schaubold *Forschritte der Mineralogie Kristallographie und Petrographie* (Band VII 1917 pp. 8-82). A more detailed account of the occurrence of the various members is given under ALBITE OLIGOCLASE ANDESINE LABRADORITE BYTOWNITE ANORTHITE. See also FELDSPAR (C. E. T.)

**PLAGUE**, in medicine a term formerly given to any epidemic disease causing a great mortality but now confined to a specific infectious fever caused by *b. pestis*.

**History to 1880**—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus who lived in the time of Trajan preserved in the *Collections of Orbasius*. Rufus speaks of the buboes called pestilential as being specially fatal and as being found chiefly in Libya Egypt and Syria. This passage shows the antiquity of the plague in northern Africa which for centuries was considered as its home. It is not till the 6th century of our era that we find bubonic plague in Europe as a part of the great cycle of pestilence which lasted fifty years and spread over the whole Roman world beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were the plague cannot now be said but it is possible the pestilences in England chronicled by Bede in the years 664 672 679 and 683 may have been of this disease especially as in 690 *pestis inguinaria* is again recorded in Rome.

In the great cycle of epidemics in the 14th century known as the Black Death some at least were bubonic plague. The mortality of the black death was as is well known enormous. It is estimated in various parts of Europe at two thirds or three fourths of the population in the first pestilence in England even higher but some countries were much less severely affected. Hecker calculates that one fourth of the population of Europe or 5 millions of persons died in the whole of the epidemics.

**The Great Plague of London**—The great plague of 1664-1665 must not be regarded as an isolated phenomenon. Plague had recurred frequently in all parts of Europe in the 15th 16th and 17th centuries. Nevertheless in London the preceding years had been unusually free from plague and it was not mentioned in the bills of mortality till in the autumn of 1664 (Nov. 2) a few isolated cases were observed in Westminster and a few occurred in the following winter which was very severe. About May 1665 the disease again became noticeable and spread but somewhat slowly. Boghurst a contemporary doctor notices that it crept down Holborn and took six months to travel from the western suburbs to the eastern through the city. The mortality rapidly rose from 43 in May to 590 in June 6137 in July 17036 in August 31159 in September after which it began to decline. The total number of deaths from plague in that year according to the bills of mortality was 68596 in a population estimated at 460000 out of whom two thirds are supposed to have fled to escape the contagion. This number is likely to be underestimated since the 6432 recorded deaths from spotted fever many were probably really from plague though not declared so to avoid painful restrictions. In December there was a sudden fall in the mortality which continued through the winter but in 1666 nearly 2000 deaths are recorded.

According to some authorities the plague was imported into London by bales of merchandise from Holland which came originally from the Levant according to others it was introduced

<sup>1</sup>Lib. xlv cap. 17—*Oeuvres de Orbasius* ed. Bussemaker and Daremberg (Paris, 1851) in 607.

by Dutch prisoners of war. From London the disease spread widely over England.

After 1666 there was no epidemic of plague in London or any part of England though sporadic cases appear in bills of mortality up to 1679 and a column filled up with 0 was left till 1703 when it finally disappeared. The disappearance of plague in London was attributed to the Great Fire but no such cause existed in other cities. It has also been ascribed to quarantine but no effective quarantine was established till 1703 so that the cessation of plague in England must be regarded as spontaneous.

But this was no isolated fact. A similar cessation of plague was noted soon after in the greater part of western Europe. In 1666 a severe plague raged in Cologne and on the Rhine which was prolonged till 1670 in the district. In the Netherlands there was plague in 1667-1669 but there are no definite notices of it after 1672. France saw the last plague epidemic in 1668 till it reappeared in 1700. In the years 1675-1684 a new plague epidemic appeared in North Africa, Turkey, Poland, Hungary, Austria and Germany progressing generally northward. Malta lost 11,000 persons in 1675. The plague of Vienna in 1679 was very severe causing 76,000 or probably more deaths. Prague in 1681 lost 8,000 by plague. Dresden was affected in 1680. Magdeburg and Halle in 1680—in the latter town with a mortality of 4,397 out of a population of about 10,000. Many North German cities suffered about the same time but in 1683 the plague disappeared from Germany till the epidemic of 1707. In Spain it ceased about 1681. In Italy certain cities were attacked till the end of the century but not later (Hirsch).

The plague epidemics in Egypt between 1833 and 1845 are very important in the history of plague since the disease was almost for the first time scientifically studied in its home by skilled European physicians chiefly French. The disease was found to be less contagious than reported to be by popular tradition and most of the French school went so far as to deny the contagiousness of the disease altogether.

An outbreak of plague in 1878-1879 on the banks of the Volga caused a panic throughout Europe and most European governments sent special commissions to the spot. The British commissioners were Surgeon Major Colvill and Dr J. F. Payne who like all the foreign commissioners arrived when the epidemic was over. In the opinion of Dr Payne the real beginning of the disease was in the year 1877 in the vicinity of Astrakhan and the sudden development of the malignant out of a mild form of the disease was no more than had been observed in other places.

**Plague in India**—It used to be held as a maxim that plague never appeared east of the Indus nevertheless it was observed during the 19th century in more than one distinct centre in India. So long ago as 1815 the disease appeared in Guzerat, Kattywar and Cutch after three years of severe famine. It reappeared early next year in the same locality when it extended to Sind as far as Hyderabad and in another direction south east as far as Ahmedabad and Dhollerah. But it disappeared from these parts in 1820 or early in 1821 and was not heard of again till July 1836 when a disease broke out into violence at the town of Pali in Marwar in Rajputana. It spread from Pali to the province of Meywar but died out spontaneously in the hot season of 1837.

In 1823 (though not officially known till later) an epidemic broke out at Kedarnath in Garhwal a sub-district of Kumaon on the south west of the Himalayas on a high situation. In 1834 and 1836 other epidemics occurred which at last attracted the attention of the government. In 1849-1850 and again in 1852 the disease raged very severely and spread southward. In 1853 Dr Francis and Dr Pearson were appointed a commission to inquire into the malady. In 1876-1877 another outbreak occurred. The symptoms of this disease called *maha murree* or *mahamari* by the natives were precisely those of oriental plague. The feature of blood spitting, to which much importance had been attached appeared to be not a common one. A very remarkable circumstance was the death of animals (rats and more rarely snakes) at the outbreak of an epidemic. The rats brought up blood and the body of one examined after death by Dr Francis showed an affection of the lungs.

**History Since 1880**—In 1880 plague existed or had existed with or without in the following parts of the world: (1) Bengal, Africa (2) Persia, Kurum (3) Iraq on the Tigris and Euphrate (4) the Air country western Arabia (5) on the lower Volga, Russia (6) northern Persia and the shores of the Caspian (7) Kumaon and Garhwal India (8) Yunnan and Pakhoi China.

The most striking feature of the early history of plague is the gradual recession of plague from the west after a series of exceptionally destructive outbreaks extending over several centuries and its disappearance from Europe. Western countries were the first to be freed from its presence namely England, Portugal and Spain. From all the east it finally disappeared about 1680 at the close of a period of pandemic prevalence. Northern and central Europe became free about 1714 and the south of France in 1717. The last outbreak in northern Russia occurred in 1710. After this plague only appeared in the south east of Europe where in turn it gradually died away during the first half of the 19th century. In 1841 its long reign on this continent came to an end with an isolated outbreak in Turkey. From that time until quite recently it remained extinct except in the East. The province of Astrakhan where a very small and limited outbreak occurred in 1878 is politically in Europe but geographically it belongs rather to Asia. And even in the East plague was confined to more or less clearly localized epidemics. It showed no power of pandemic diffusion. In short if we read the history of this disease as a whole it appears to have lost such power from the time of the Great Plague of London in 1665 which was part of a pandemic wave until the present day. There was not merely a gradual withdrawal eastward lasting nearly two hundred years but the outbreaks which occurred during that period violent as some of them were showed a constantly diminishing power of diffusion and an increasing tendency to localization. The sudden reversal of that long process is therefore a very remarkable occurrence. Emerging from the remote endemic centres to which it had retreated plague has once more taken its place among the zymotic diseases with which modern science has to reckon.

**Diffusion**—Visitations of cholera can be traced definitely to a point of origin often in India (see CHOLERA). Similarly though not with equal precision a wave of influenza was shown to have started from central Asia in the spring of 1889 to have travelled through Europe from east to west to have been carried thence across the sea to America and the Antipodes until it eventually invaded every inhabited part of the globe (see INFLUENZA). In both cases no doubt remains that the all important means of dissemination is human intercourse. The movements of plague cannot be followed in the same way. With regard to origin several endemic centres are now recognized in Asia and Africa namely: (1) the district of Assyr in Arabia on the eastern shore of the Red Sea (2) parts of Mesopotamia and Persia (3) the districts of Garhwal and Kumaon in the North West Provinces of India (4) Yunnan in China (5) East and Central Africa. The last was discovered by Dr Koch.

The following is a list of countries in which plague is known to have been present in each year (see Local Government Board's Reports): 1880 Mesopotamia 1881 Mesopotamia Persia and China 1882 Persia and China 1883 China 1884 China and India (as *mahamari*) 1885 Persia 1886 1887 1888 India (as *mahamari*) 1889 Arabia Persia and China 1890 Arabia Persia and China 1891 Arabia China and India (as *mahamari*) 1892 Mesopotamia Persia China Russia (in central Asia) 1893 Arabia Persia China Japan Russia East Africa, Madagascar and China and India (as *mahamari*) 1895 Arabia and China 1896 Arabia Asia Minor China Japan Russia and India (Bombay) 1897 Arabia China Japan India Russia and East Africa 1898 Arabia Persia China Japan Russia East Africa Madagascar and Vienna, 1899 Arabia Persia China Japan Mesopotamia East Africa, West Africa, Philippine Islands, Straits Settlements Madagascar, Mauritius Réunion Egypt, European Russia Portugal, Sandwich Islands, New Caledonia Paraguay Argentine Brazil 1900, to the foregoing should be added Turkey Australia California Mexico and Glasgow in 1901 South Africa

and in 190 Russia chiefly at Odesa.

In 1896 plague appeared in the city of Bombay. The infection spread gradually and slowly at first but during the next three months of 1897 not only was the town of Bombay severely affected but districts around it. The prevalence was a little notably Poon, Karachi, Cutch, Malabar, and the Deccan. The following figure are the mortality of Bombay and India as well as the total mortality in India.

Year	Bombay Presidency (including Calcutta)	India (including Bombay)	Total
1896			17
1897		4 10	4 14
1898	10	8 131	8 141
1899	3 04	36 59	102 63
1900	38 412	3 196	41 608
1901	8 69	1 5 51	10 220
1902	5 961	154 5	160 416
1903	6 680	81 61	67 291
1904	75 438	3 95	79 393
1905	126 054	1 56	127 610
1906	59 619	51 5	111 124

In 1900 there was an outbreak of plague in Australia. The total number of cases reported in Queensland was only 13 with 53 deaths. In Sydney there were 303 cases with 103 deaths, a case mortality of 34%. The infection is supposed to have been brought from Noumea in New Caledonia where it was present at the end of 1899. Plague in Glasgow was on a still smaller scale. It began so far as could be ascertained in August 1900 and during the two months it lasted there were 34 cases and 15 deaths. Once more the disease was not at first recognized and its origin could not be traced. In 1901 plague invaded South Africa and obtained a distinct footing both at Cape Town and Port Elizabeth. The total number of cases down to July was 160 with 362 deaths; the number of Europeans attacked was 196 with 68 deaths, the rest being natives, Malays, Indians, Chinese and negroes. With regard to Great Britain a few ship-borne cases had to be dealt with at the ports.

**Causation.**—Plague is a specific infectious fever caused by the *bacillus pestis* which was identified in 1894 by Kitasato and subsequently but independently by Yersin (see BACTERIA and DISEASE). It is found in the buboes in ordinary cases in the blood in the so-called septicaemic cases and in the sputum of pneumonic cases. It may also be present in the urine. *Post mortem* it is found in great abundance in the spleen and liver. Nothing is known of its natural history outside the body but on cultivation it is apt to undergo numerous involution forms. Its presence in a patient is regarded as positive diagnostic proof of plague but failure to find or to identify it does not possess an equal negative value and should not be too readily accepted. It is quite clear from the extreme variations in the severity of the illness that the resisting power of individuals varies greatly. According to the Plague Research Committee of Bombay the predisposing causes are those leading to a lower state of vitality of which insufficient food is probably the most important. There is no evidence that age, sex or race exercises a distinct predisposing influence. The largest incidence in Bombay was on young adults but then they are more numerous and more exposed to infection because they go about more than the younger and the older. Similarly the comparative immunity of Europeans in the East may be explained by their different conditions of life. It is doubtful whether the distinction drawn between *pestis minor* and *pestis major* has a real aetiological basis. Very mild cases occurring in the course of an outbreak of typical plague may be explained by greater power of resistance in individuals but the epidemic prevalence of a mild illness preceding the appearance of undoubted plague suggests some difference or modification of the exciting cause. Of course plague does not stand alone in this respect. Epidemic outbreaks of other diseases—for instance cholera, diphtheria and typhoid fever—are often preceded and followed by the prevalence of mild illness of an allied type.

**Clinical Characters.**—One of the results of recent observation

is the classification of plague cases under the three heads (1) bubonic, (2) pneumonic, (3) septicaemic. This classification is a little more than the mere and three varieties are just as much part of the same disease as the three varieties of cholera are part of the same disease. The word 'bubonic' has reference to the circumscribed death of the patient, not to the fact that non-bubonic types are also recorded.

The three varieties within the wide limits and exhibits all the variations from a mere indisposition which may pass almost unnoted to an extreme violence only equalled by the most violent form of cholera. The milder cases are always bubonic, the other varieties are invariably severe and almost always fatal. Incubation is generally from four to six days but it has been observed a short as three hours and as long as ten days (Bombay Research Committee). As a rule the onset is sudden and well marked.

(1) Bubonic cases usually constitute three-fourths of the whole and the symptoms may therefore be called typical. In a well-marked case there is usually an initial rigor—in children convulsions—followed by a rise of temperature with vomiting, headache, giddiness, intolerance to light, pain in epigastrium, back and limbs, sleeplessness, apathy or delirium. The headache is described as splitting, delirium is of the buprestic-like delirium tremens. The temperature varies greatly, it is not usually high on the first day—from 101° to 103°—and may even be normal but sometimes it rises rapidly to 104° or 105° or even 107° F. A fall of two or three degrees on the second or third day has frequently been observed. The eyes are red and inflamed, the tongue is somewhat swollen and at first covered with a thin white fur except at the tip and edges but later it is dry and the fur yellow or brownish. Prostration is marked. Constipation is the rule at first but diarrhoea may be present and is a bad sign. A characteristic symptom in severe cases is that the patient appears dazed and stupid, is thick in speech and staggers. The condition has often been mistaken for intoxication. There is nothing however in all these symptoms positively distinctive of plague unless it is already prevalent. The really pathognomonic sign is the appearance of buboes or inflamed glands which happens early in the illness usually on the second day, sometimes they are present from the outset, sometimes they cannot be detected before the third day or even later. The commonest seat is the groin and next to that the axilla, the cervical, submaxillary and femoral glands are less frequently affected. Sometimes the buboes are multiple and on both sides but more commonly they are unilateral. The pain is described as lancinating. If left they usually suppurate and open outwards by sloughing of the skin but they may subside spontaneously or remain hard and indurated. Petechiae occur over buboes or on the abdomen but they are not very common except in fatal cases when they appear shortly before death. Boils and carbuncles are rare.

(2) Pneumonic plague was observed and described in many of the old epidemics but its precise significance was first recognized by Childe in Bombay. He demonstrated the presence of the bacilli in the sputa and showed that the inflammation in the lungs was set up by primary plague infection. The pneumonia is usually lobular, the onset marked by rigors with difficult and hurried breathing, cough and expectoration. The prostration is great and the course of the illness rapid. The breathing becomes very hurried—forty to sixty respirations in the minute—and the face dusky. The expectoration soon becomes watery and profuse with little whitish specks which contain great quantities of bacilli. The temperature is high and irregular. The physical signs are those of broncho-pneumonia, oedema of the lungs soon supervenes and death occurs in three or four days.

(3) In septicaemic cases the symptoms are those of the bubonic type but more severe and without buboes. Prostration and cerebral symptoms are particularly marked, the temperature rises rapidly and very high. The patient may die comatose within twenty-four hours, but more commonly death occurs on the second or third day. Recovery is very rare.

The case mortality of plague still remains exceedingly high. The lowest recorded is 34% in Sydney, and the highest 95% at

Hong Kong in 1899. During the first few weeks in Bombay it was calculated by Dr Viegas to be as high as 99%. It is very much higher among Orientals than among Europeans. In the Bombay hospitals it was about 70% among the former and between 30% and 40% among the latter which was much higher as in Oporto, Sydney and Cape Town. It appears therefore that plague is less fatal to Europeans than cholera. The average duration of fatal cases is five or six days. In the House of Correction at Byculla where the exact period could be well observed it was five and a half days. Patients who survive the tenth or twelfth day have a good chance of recovery. Convalescence is usually prolonged. Second attacks are rare but not unknown.

**Diagnosis**—When plague is prevalent in a locality the diagnosis is easy in fairly well marked cases of the bubonic type but less so in the other varieties. When it is not prevalent the diagnosis is never easy and in pneumonic and septicaemic cases it is impossible without bacteriological assistance. The earliest cases have hardly ever been even suspected at the time in any outbreak in a fresh locality. It may be taken at first for almost any fever particularly typhoid or for venereal disease or lymphangitis. In plague countries the diseases with which it is most liable to be confounded are malaria, relapsing fever and typhus or broncho pneumonia in pneumonic cases.

**Dissemination**—The investigations of the Indian plague commission working in conjunction with the advisory committee showed that bubonic and septicaemic plague are transmitted by the agency of fleas. Highly susceptible animals are not infected by their plague stricken fellows so long as fleas are excluded from the cages but with the introduction of these ectoparasites the disease forthwith spreads from the sick to the healthy. Subsequent experience has confirmed the main findings of the commission and outbreaks of human plague are unquestionably mere extensions of preceding or concurrent plague affecting animals. Rats (*Rattus rattus*) are of outstanding importance as reservoirs of infection through their close association with man but marmots (*Arctomys bobac*), gerbilles (*Tatera lovengulæ*) and ground squirrels (*Citellus beecheyi*) have been responsible for epidemic outbreaks in China, South Africa and California respectively.

The plague commission concluded that the disease can be transmitted by the faeces of infected fleas but did not state that this is the usual method of spread. Bacot and Martin later demonstrated that the entrance to the flea's stomach becomes obstructed by a mass of plague bacilli. Such fleas in their persistent efforts to feed merely succeed in distending the gullet with blood which now contaminated regurgitates on to the skin of the host. The organisms then enter the body either through the flea's bite or through some abrasion of the skin.

The flea most commonly incriminated as a plague vector is *Xenopsylla cheopis* but several other species of rat fleas (*Ceratophyllus fasciatus*, *Stivalis ahalae*), the common mouse flea (*Lepopsylla musculi*), the dog flea (*Ctenocephalus canis*), a marmot flea (*Ceratophyllus silantjevi*) and the human flea (*Pulex irritans*) amongst others are proven carriers of plague.

**Epidemiology**—Laborious studies on the biology of fleas have added to our knowledge of the epidemiology of plague. These insects cannot withstand desiccation and their survival apart from their host is proportional to the rate at which they lose moisture. Bacot and Martin (1944) found the water content of fleas to be 80% of their weight and death occurred before the loss of water had reached 60% of their weight. This goes far to explain the observation that plague does not maintain itself in epidemic form when the temperature rises above 80°F accompanied by a saturation deficiency of over 30 of an inch.

The seasonal variations in the spread of plague have been recognised for many centuries. In temperate countries epidemics attain their maximum in the summer months whereas in tropical climates the onset of hot dry weather brings an existing epidemic to an end. In each case the peak of the plague curve coincides with meteorological conditions most favourable to the activity and longevity of fleas. In contradistinction to the foregoing pneumonic plague once established spreads independently of animals and fleas. In outbreaks of ordinary plague a secondary

involvement of the lung supervenes in a small proportion of cases and if atmospheric and environmental conditions favour the survival and transmission of the bacilli an epidemic of pneumonic plague may result the virus being transmitted from the cougher to the victim up to a range of about three feet.

**Treatment and Prophylaxis**—Unfortunately there is no plague specific serum to be really effective must be given before the symptoms of the disease are manifest an impossible procedure in most cases. Still when available serum should be administered intravenously in doses of 80–100 c.c.s. and repeated. Some advocate injection of tincture of iodine (7–10 minims) or other antiseptics intravenously and also into the buboes. These measures are of doubtful benefit. Buboes showing signs of suppuration should be incised. Otherwise treatment is on general lines and cardiac stimulants should be administered early.

So long as members of a community are content to live in association with rats and fleas correlative plague is a likely result. Meanwhile plague prophylaxis consists mainly of warfare against rats in the hope of ultimately banishing them from human habitations and from contact with man. Any general elimination of these pests over wide areas is a slow costly and usually impracticable affair and all that can be achieved in most cases is some degree of palliation by rat proofing of grain stores, wharves and other places which serve as centres for the dissemination of plague. Destruction of rats by trapping and poisoning is a commendable procedure but of itself will never eradicate endemic plague for the losses in the rat population are quickly made good if survivors are provided with food and harbourage. An important measure of personal prophylaxis is inoculation with anti plague vaccine which affords a good degree of protection. Persons entering plague infected houses should wear gaiters and otherwise render their clothing as flea proof as possible. If there is any suspicion of pneumonic plague goggles and masks made of several layers of fine gauze should be worn without fail.

**PLAICE** (*Pleuronectes platessa*) a flat fish that ranges from Iceland and northern Europe to south of Great Britain and one of the most important commercial fishes of the North sea. Other species of somewhat similar form with large eyes on the right side and with a small terminal mouth are the dab and flounder from these the plaice is easily distinguished by the red spots scattered over the body. The pharyngeal bones are strong and bear large blunt teeth used for crushing the shells of the bivalves that are the principal food of this species. A length of more than 30 in. and a weight of 8 lb. may be attained but nearly all the fish marketed are less than half that length.

**PLAINFIELD**, a city of Union county New Jersey U.S.A. 24 m. W. by S. of New York city served by the Baltimore and Ohio, the Central of New Jersey and the Reading railways. Pop. (1920) 27,700 and 34,400 in 1930 by Federal census. With the adjacent boroughs of North Plainfield and South Plainfield the population of the Plainfields was estimated locally at nearly 50,000. Situated on high ground among the charming Watchung hills well laid out and strictly zoned Plainfield is one of the most attractive of the residential suburbs of New York. There are five golf courses in and near the city clubs devoted to various sports and recreations a symphony orchestra a community playhouse and excellent public and private schools. While manufacturing is relatively unimportant there are substantial industries and the aggregate output in 1927 was valued at \$14,708,345. The city's

assessed valuation for 1908 was \$45,500. Settled here here dates from 1864. In 1860 a grist mill was erected and for several years the village was called Milltown. The township of Plainfield was created out of the township of Westfield in 1867, and the city was chartered in 1867.

**PLAINS INDIANS.** The tribes of the central portion of the North American continent on the open plain and prairie prairies extending from Alberta and Saskatchewan to Texas and from the Rocky Mountains almost to the Mississippi river formed a natural unit both in environment and culture. Essentially this territory is the habitat of the American bison (buffalo), and on this animal the Plains tribes primarily depended for food, shelter, clothing and many utensils, and to its habits many of their customs were adapted. The eastern tribes in the prairies seasonally combined bison hunting and maize farming; the western ones in the plains proper were wholly nomadic. Originally they transported their tents and belongings on travois frames dragged by dogs. After the introduction of the horse by the Spaniards beginning about 1650 this animal gradually replaced the dog; tribal movements became freer while their numbers augmented and their culture elaborated. They camped in large circles of tipis, conical tents of bison skins supported by long poles leaning on a primary tripod (or four poles)—a highly specialized convenient dwelling quickly pitched and struck. Cooking was by roasting or with hot stones in bison rawhide containers; meat predominated heavily in the diet. Property and food were stored and transported in rawhide bags and parfleches. Clothing was of deer (antelope etc.) skins supplemented by bison robes and was well tailored, ample, comfortable and often highly ornamented with embroidery of porcupine quills, later beads. Social organization was simple: matrilinear clans, patrilinear clans or non-exogamic bands according to tribe. Warfare was constant, being carried on partly for profit (horse-raiding) but chiefly for honour, a man's career depending directly on the prestige of his war exploits; hence arose the system of counting coups, that is publicly recounting blows struck on enemies. The best known ritual was the so-called Sun dance. Most other rites were conducted by societies which among some tribes were age-graded. Supernatural power was sought in visions by most men; warriors as well as curers. There were sacred bundles for tribes, clans and societies; these were fetiches preserved for generations.

The Plains tribes are proud, brave, outspoken and direct and possess an unusual sense of individuality and personality. The physique is exceptionally tall, rangy and hardy. With their long braided hair, fringed costume, eagle feather war bonnets mounted on ponies with tipis as a background the Plains tribes have captured the imagination of recent generations of whites and pass popularly as the most representative of Indians. The most typical Plains tribes are the Dakota, Assiniboiné, Blackfeet, Gros Ventre, Arapaho, Cheyenne, Kiowa, Comanche; others are the Sarsi, Plains Cree, Pawnee, Ojibwa, Wind River, Shoshone, Mandan, Hidatsa, Arikara, Pawnee, Omaha, Ponca, Iowa, Oto, Missouri, Kansas, Osage, Wichita, Kiowa, Apache, and among the tribes in or across the Rocky mountains the Kootenay, Flathead, Nez Perce, Bannock, Ute and Jicarilla Apache have been especially influenced by Plains culture. The preponderant stock is the Siouan; next the Algonkin, Shoshonean, Athabascan, Caddoan are also each represented by two or more tribes.

See C. Wissler, *Indians of the Plains* (Am. Mus. Nat. Hist. 1912) for a general summary and monographs or books by G. Catlin, W. P. Clark, E. H. Curtis, G. A. Dorsey, J. O. Dorsey, A. C. Wissler (A. L. K.).

**PLAINSONG or PLAIN CHANT.** A general term for a certain style of unisonal music comprising chiefly the church music called Gregorian, which belongs to Rome and that called Ambrosian, which hails from Milan. But the other Western collections of church music much less well known than these and a good many groups of Eastern church music could also quite properly be put under this heading.

**Origin.**—There are various factors in the genesis of music which determine its essential characteristics. Music intended for a

single use is necessarily regular in its rhythm, so also though less necessarily in its melody which is set to metrical verse. On the other hand music fitted to a prose text is necessarily irregular. Thus there are different kinds of rhythm in music ranging from strict time to the free ebb and flow of movement. Again, one music arises from recitation and the need to declaim on words artistically and audibly, while other music arises at melody that is to say a succession of sound which is pleasant for its own sake and would be so independently of any words.

The ecclesiastical music which is called plain song is so named because it is unmeasured music, not regular in rhythm, a *cantus planus* as contrasted with *cantus mensuralis* or measured music. It is this feature that chiefly differentiates it from modern music, and at the same time allies it with such things as sea-chanties, counting out rhyme, and the like. The Christian church like other worshipping bodies requires euphonious sounds for the recitation of its psalms and for the reading of its scriptures in public. As these passages are not (for the most part) written in any strict metre, the music to be provided is essentially a plain chant; there are several classes of such plain song.

**Influence of the Psalter.**—The chief influence in this evolution has been that of the Psalter. Hebrew poetry follows a metrical system, but this disappears in translation. There survives, however, a more obvious feature of the original, viz. its parallelism. This consequently becomes a prominent characteristic of certain sorts of plain song, so that the chants directly derived from the psalms take a binary form. The recitation demands a reciting note on which the text can be freely recited in its own rhythm and shape. If this note alone is used, the effect soon becomes in the strict sense of the word monotonous. Therefore the music adopts the natural tendency of the voice to rise up to its reciting note at the beginning and to drop down from it at the end of the phrase. Thus arises the commonest chant form of plain song, consisting of (1) an intonation, (2) recitation and (3) cadence in each half-verse. The psalm tones, whether Gregorian or Ambrosian, take this shape, and the form is capable of more or less elaboration for the psalms. The Gregorian tones are very simple; more elaborate forms of them are used for the Gospel canticles and still more developed forms for the Introits. A limit is naturally set to the amount of elaboration either (a) when whole psalms are to be sung at length, or (b) when they are to be sung by the whole congregation. When however select verses only are sung and are sung by trained singers, there is far more scope for elaboration, and the developed responds used both at Mass and at the Choir office exhibit this chant form in a highly ornamental shape.

The chief development occurs in the Cadences. In its simplest form the musical cadence affects only the last syllable, e.g. there is the drop of a minor third. Next it concerns the last two syllables. These two simple cadences are familiar even to those who do not know the Gregorian tones from their being used in the Versicles and Responses of the Prayer Book. The more elaborate cadences naturally followed the cursus used by Latin prose writers of the best, or at any rate the most formal style. In the responds a five-syllable cadence is constantly in use and often in a highly decorated form.

All this music arises out of the recitation of psalms. For the purpose of declaiming the lessons of Scripture only the simpler inflexions were used, and the same is true of the prayers or collects, except a few which are of exceptional solemnity, such as the

Preface or the Lord's Prayer as used in the consecration prayer at Mass or the Hallowing of the Font at Baptism.

**Antiphons.**—Next to be considered is a totally different way of beautifying the recitation of psalms or other prose texts. Instead of elaborating the chant itself, there was interpolated between the verses a suitable refrain. These refrains came to be known as antiphons, and thus side by side with the older method which came to be called 'responsorial' from the responds which represented it at its fullest development, there arose the newer 'antiphonal' method. The former music developed from recitation and even in its most elaborate forms in more or less degree it hung round a reciting note. The antiphons were purely melodic and the method had its quality and meaning determined

not by reference to a dominant reciting note but to the final note on which it ultimately came to rest

Antiphonal music underwent modification and development just as the responsorial music did. Its relation to the psalm altered the singing of the refrain after each verse survived mainly in processional use. In choir office the refrain was dropped so that it was sung only at the beginning and end of the psalm or else in a curtailed form at the beginning and in full only at the end. In the psalmody of the Mass the opposite form of abbreviation was adopted. For at the Introit and the Communion the psalm became restricted to only one or two verses and at the Communion it ultimately disappeared altogether leaving the Antiphon alone.

Some antiphons composed on a large scale arose independently of any connection with a psalm. These were used especially in processions. Others retained the idea of a psalm verse but utilized for such verses not the normal psalm tones but independent melodies perhaps as elaborate as the psalm itself. Such antiphons especially prevailed at the Offertory in the Mass.

The greater part of the classical Gregorian plain chant falls into one or other of these two classes. The amount of elaboration depended mainly upon two considerations: (1) the importance of the occasion and (2) the capacity of the singers. A great festival or a specially dignified part of the service demanded richer treatment and the trained singers undertook more difficult music than the congregation, the soloists, or the choir generally.

**The Gregorian Music**—The *Cantilena Romana* Gregorian chant proper is thus a body of music purely vocal and ecclesiastical, evolved by the Papal choir in the course of the fifth and sixth centuries. This was codified in the time of St. Gregory (c. 540–604) (qv) and it stands as the basis of all the Gregorian Music. The Milanese tradition was similar but less artistic. It is called Ambrosian (see ST. AMBROSE) but the term has no historical significance as the term Gregorian has. A comparison of these two families of plain chant brings out clearly the comparative crudity of the Ambrosian tradition as distinct from the artistic balance and delicate finish of the classical Gregorian chant. The same is true also of such other specimens of Western ecclesiastical chant as are known. The Gregorian reform marks the close of a golden age of classical monody. The middle ages subsequent to St. Gregory produced nothing so good, and the later part of them while producing only little and decadent plainsong deprived also the form of the classical tradition.

Something more must be said to describe the contents of the Gregorian corpus and also to explain the musical theory which lay behind it. The music covers the whole series of services of the Roman rite but principally the Mass and the series of daily Choir Services. At the Mass some of the things sung are invariable while others change according to the Sunday or Festival or occasion generally. The unchanging elements are chiefly the *Kyrie*, *Credo*, *Sanctus*, *Agnus dei*, and *Gloria in excelsis*. For these the old tradition provided little or no change of music and what there was followed very simple lines suitable for congregational singing. The variable elements were principally the Introit psalm, the Gradual, respond, the Offertory antiphon, and the Communion antiphon. The Gradual was at times replaced or supplemented by an Alleluia with a Verse attached to it or by a Tract. The Alleluia belonged specially to festive seasons and occasions, the Tract to penitential. Neither of these falls exactly into either of the two chief categories responsorial and antiphonal. The Tract is a very ancient but elaborate type of the developed psalmody; the Alleluia was an innovation which came in towards the end of the classical period and extended beyond it into the Silver Age when little else was being composed.

For the choir offices there was provided a large number of antiphons to go with the psalmody and a considerable number of responds which mainly served as interludes between the lessons at Mattins. When hymnody began with St. Ambrose it was taken up and incorporated into the services by the monks but Rome was for a long time too conservative to admit hymns. The plain-song hymn tunes are, in the nature of the case, more definitely metrical than the other music but they retain a considerable

freedom of movement and are not measured like modern hymn tunes.

**Underlying Musical Theory**—The musical theory which lies behind this music is based on a series of eight scales or Modes. It is the old diatonic scale of the Greek theorists (equivalent to the white notes of the pianoforte with the addition of B) but the modes themselves are different from the old Greek modes and the use of the old Greek names only leads to confusion. The eighth mode system was probably the same as the *οκτώηχος* which underlies the Eastern church music but the origins are obscure alike in East and West. The scheme seems to go back at least to St. John of Damascus (c. 150) but it is known in the West only in theoretical treatises derived through the Byzantine teachers at the court of Charlemagne at the end of the eighth century.

The eight modes are really four pairs, each pair being founded on the same note, the one scale (called Authentic Mode) being an octave ranging above the foundation or final note, the companion (called Plagal) being an octave ranging above and below it.

First	}	A B C D E F G a b c d
Second		
Third	}	B C D E F G a b c d e
Fourth		
Fifth	}	C D E F G a b c d e f
Sixth		
Seventh	}	D E F G a b c d e f g
Eighth		

Each of these pairs has a character or tonality of its own dependent upon the position which the semitones have in the scale. None is similar to the major or minor key of modern music. It is this tonality which gives the special character to plain song melody. Some theorists have reckoned twelve or even fourteen Modes but this is unnecessary. So far as pitch goes, the range of two octaves covered by the eight modes is adequate, and so far as tonality is concerned, the new modes would be only the same as the first four or six over again with the Bb used instead of B. (For further discussion of the Modes see HARMONY.)

This modal theory does not fully account for all the procedure of the classical plain chant (practice always surpasses theory) but these eight modes are clearly the foundation of this music whether responsorial or antiphonal.

In the middle ages the *cantilena Romana* was handed on by tradition from St. Gregory's days. In the ninth century it was recorded in the notation reames. The notation on a staff which began a couple of centuries later while it fixed accurately the pitch of each note failed to reproduce the rhythmical delicacies which the earlier notation had recorded. Hence the recent renaissance of classical plain song has been based on a return to the reames as interpreted by subsequent tradition.

The revived interest in music of the Carolingian era stimulated composition which had been long in abeyance. Not only new music for new feasts arose but fresh settings of the Ordinary (fixed elements) of the Mass. While the old music was preserved it was padded out with new and inferior interpolations called by the generic name of 'Tropes'. These had their day and pervaded all the church music for a century or more but then they went out of fashion leaving only two considerable legacies: (a) a further series of settings of the 'Ordinary', (b) the new form of rhythmical or (later) metrical poem called Sequences or Proses. These survived in considerable numbers down to the sixteenth century but at the present time only a few are in use.

**Modern Revival**—The rise of the art of harmony beginning from the eleventh century diverted attention from the monody of plain chant and part singing had the effect of 'measuring' the music so that it fell into regular time and was no longer free or plain. Under these influences the old plain-song was progressively debased and as harmonized music went up plain chant went down. Not until the nineteenth century did this degradation cease. The efforts then made in various quarters to recover alike the true rhythm and tonality of the old music have culminated in the work of the Benedictines of Solesmes.

followers and in the revival which has produced the new Mexican Gradual and is producing by degrees a restored Anabaptist as well. With the recovery of the music has come a new interest upon its use and study as being the official music of the Roman Church.

**PLAINTIFF** see PRACTICE AND PROCEDURE

**PLAINVIEW**, a city of northwestern Texas, USA, 10 m W by N of Fort Worth on the southern plains of the Panhandle at an altitude of 300 ft, the county seat of Hale county. It is on Federal highways 50 and 55, and is served by the Santa Fe and the Colorado and Southern railway systems. Pop. (1930) 3,959. In 1908 by the Federal census. It is the trade centre of 5,000 sq m of farming territory (partly irrigated), raising chiefly cotton, wheat and grain sorghums. The Texas Panhandle Plains Dairy Show is held here annually. The site for the city was surveyed in 1888. The settlement remained a mere trading post for the cattlemen who then occupied the entire region until the railway reached it in 1901, whereupon it was incorporated as a city. By 1921, it had an assessed valuation of \$644,306. Diversified farming began to displace ranching about 1915 and the cultivation of cotton began in 1918.

**PLANCK, MAX** (1858– ) German physicist was born at Kiel on April 23, 1858. He studied at the universities of Munich and Berlin, became an assistant in Munich University and was subsequently appointed a professor in Kiel (1885) and in Berlin (1889). Planck devoted himself to the study of theoretical physics and in particular to that of thermodynamics. His lectures on this subject appeared in book form and were translated into English, French and Russian. He gained international fame by his *Law of Radiation* (1901) which asserts that the energy of radiation is emitted and absorbed in integral multiples of certain indivisible quanta of energy which depend on the frequency of oscillation of the electrons. In 1912 Planck extended this quantum theory ( $q \propto \nu$ ) to all kinds of energy and added the assumption that only emission proceeds discontinuously in quanta while absorption is continuous. On this assumption he was able to derive the distribution of energy in the spectrum of black body radiation. The quantum theory has been developed and modified by him and many other physicists but the foundation was laid by Planck's work on black body radiation. In 1918 he was awarded the Nobel Prize for physics. Planck became editor of the *Annalen der Physik*. He was elected a foreign member of the Royal Society in 1926.

Among his works are *Die Entstehung und bisherige Entwicklung der Quantentheorie* (1900, Eng. trans. 1921), *Vorlesungen über die Theorie der Wärmestrahlung* (1911), *Physikalische Rundblicke* (1922, Eng. trans. 1925), *Einführung in die Theorie der Elektrizität und des Magnetismus* (1922) and *Die Ableitung des Strahlungsgesetzes* (1923).

**PLANE** The simplest definition of plane given by the Greek geometers is that of Heron of Alexandria (c. 200)—a surface such that if a straight line passes through two points on it, the line coincides wholly with it at every spot all ways. Crelle (1834) defined it as the surface containing all the straight lines (throughout their entire lengths) passing through a fixed point and also intersecting a straight line in space. (For plane a tool see EDGE TOOLS.)

See H. Schotten *Inhalt und Methode des planimetrischen Unterrichts* (Leipzig 1890, 1893). Sir T. L. Heath *The Thirteen Books of Euclid's Elements* (1926). (See also SURFACE.)

In botany plane is the common name of a handsome tree known botanically as *Platanus orientalis* (family Platanaceae), a native of Greece and western Asia, a favourite shade tree of the ancient Greeks and Romans and introduced by the latter to south-west Europe. It is one of the most successful trees in London and other large towns, the smooth face of the leaf is easily washed by rain and the periodical peeling of the bark also serves to get rid of surface deposits of soot, etc. It is a large tree with widely spreading branches and alternate palmately five-lobed leaves resembling those of the sycamore in shape, but quite harmless and of a brighter green. The bud in the leaf axil is protected during its development by the hollow base of the leaf stalk, which lifts off like an extinguisher when the leaf falls in autumn. The minute, unisexual flowers are borne in dense

pendulous heads, which contain either male or female flowers; the small seed pods are produced in a ball from which they gradually separate and drive in the readily carried by the wind. A variety of form is known in cultivation, the common one being the deeply lobed (*exfolia*) the London plane, which is usually the lobed *var. laciniata* has very deeply much lobed leaves and very large a variegated foliage.

PLANE (*PLATANUS ORIENTALIS*) SHOWING BRANCH WITH FRUITS. A BRANCH WITH DROOPING FEMALE HEADS WHICH ARE WIND POLLINATED.

age *Platanus occidentalis*, an allied species is a native of the United States, being most abundant and growing to its largest size in the basin of the lower Ohio and the Mississippi rivers. It was introduced into England early in the 17th century and is occasionally met with in western and central Europe. It is known in America as sycamore and buttonwood. It differs from *P. orientalis* in its less deeply lobed, more leathery pubescent leaves and in the usually solitary balls of fruit. Both the native sycamore and the London plane are extensively planted as ornamental trees in the eastern United States. The California sycamore (*P. racemosa*) and the Arizona sycamore (*P. Wrightii*) of the extreme South-west are much smaller than the eastern species.

**PLANER** see MACHINE TOOLS WOOD WORKING MACHINERY

**PLANET** (Gr. *πλανήτης* a wanderer) The term was applied in the ancient Ptolemaic or geocentric astronomy to the seven heavenly bodies which were observed to change their places as projected against the background of the so-called fixed stars. These bodies were the Sun, the Moon, Mercury, Venus, Mars, Jupiter and Saturn, all of which were supposed to revolve round the earth. In the modern or heliocentric astronomy (taught by Aristarchus of Samos in the third century B.C. but forgotten or neglected till revived by Copernicus in the 16th century of the Christian era) it is applied to all dark and opaque bodies in revolution round the sun, and the number of such bodies known has been greatly increased by successive discoveries. In 1781 William Herschel discovered Uranus. In 1801, on the first night of the new century,

TABLE I Elements of the Orbits of the Major Planets for the Epoch 1925 Jan 0 G M N

Planet	Sym- bol	Mean distance from sun in		Eccentricity $e$	Inclination $i$	Mean longitude of			Period of Sidereal revolution $P$	Mean daily motion
		Astronom- ical units $\alpha$	Millions of mil			Ascending node $\Omega$	Perihelion $\omega$	Planet at epoch $L$		
Mercury		0.38,099	36.0	0.205619	7.0 12.0	47 26 32.1	76 17 18.9	105 40 25.31	87.967 days	4.0923

Pluto		Reliable elements cannot yet be given. Distance at discovery about 41 units. Inclination about 17. Period probably rather less than 300 years. Planet within Neptune's orbit at perihelion.								

In mean solar days and tropical years

Piazzi discovered Ceres a small planet revolving between the orbits of Mars and Jupiter and the first of a great host of small bodies known as minor planets or asteroids while in 1846 Neptune was added to the list of major planets following on the mathematical work on the unexplained irregularities in the motion of Uranus by Le Verrier and independently by Adams (see notes on Neptune). Recently (1930 Feb.) a yet more remote planet has been found at the Flagstaff Observatory near the position predicted by the late Professor Lowell. It has been named Pluto. Most of the major planets possess moons or satellites. So far as at present known Neptune possesses one, Uranus four, Saturn nine, Jupiter nine, Mars two and the Earth one.

**Distances of the Planets.**—An empirical law expressing very closely the relative distances from the sun of the primary planets known to the ancients was discovered about the middle of the seventeenth century by Titius of Wittenburg but it was later brought into notice by Bode and is generally known as Bode's law. If a series of 4's be written down and 3 be added to the second 6 to the third 1 to the fourth and so on each of the added numbers being double its predecessor the sums of the first seven numbers are 4 7 10 16 28 52 100. These numbers divided by 10 were found to give with a surprising closeness the relative distances of the planets as far as Saturn except that no planet was known to revolve in the orbit corresponding to 8 between the orbits of Mars and Jupiter. When Uranus was discovered and found to fit in well with the next number in the series (196) the conviction was strengthened that the gap between Mars and Jupiter must be occupied by some planet and a search for the missing body was organized. But before systematic work was actually begun the little planet Ceres was found. The discovery was soon followed by others and at the present time considerably more than 1000 of these minor planets are known. They are not however actually confined to the gap above mentioned. The little planet Eros discovered by Witt in 1898 comes at perihelion within 13,000,000 miles of the earth's orbit and hence it is of special value to astronomers for the determination of the solar parallax which fixes the scale of the planetary system. Hidalgo discovered by Baade in 1922 in the most distant part of its orbit goes out as far as the orbit of Saturn and has a mean distance slightly greater than that of Jupiter. The actual distances of the greater planets from the sun in miles will be found in Table I.

**Orbits and Phases of the Planets.**—From the observations of Tycho Brahe the great Danish observer Kepler deduced the following three great laws of planetary motion—

(1) The planets move in ellipses with the sun at one focus. Hitherto it had been believed that the circle being the most perfect geometrical figure celestial motions took place in circles.

(2) The straight line from the sun to a planet (radius vector) passes over equal areas in equal times. The importance of this law was that it involves a continually varying rate of motion, which was also contrary to accepted beliefs at the time. To maintain the equal description of areas in unit time a planet must travel faster in the neighbourhood of perihelion where the radius vector is at a minimum than near aphelion where it attains its maximum value.

(3) The squares of the periodic times (the times required for the orbital revolutions of the planets) are proportional to the cubes of the mean distances (the semi-major axes of their orbits). This is known as the *harmonic law* and defines the relationship between a planet's orbital motion and its distance from the sun.

From these laws of planetary motion Newton deduced his law of universal gravitation which has achieved such remarkable successes and prepared the way for Einstein's relativity theory.

The dimensions, form and aspect of a planet's orbit as well as the position of the planet in the orbit at any time are defined by what are known as its *elements*. These are—

(1) Half the major axis, or mean distance (generally denoted by  $a$ ). This defines the *size* of the orbit.

(2) The eccentricity ( $e$ ) or the ratio of the distance of the sun from the centre of the orbit to the mean distance. This defines the *shape* of the orbit.

(3) The inclination ( $i$ ) of the orbit plane to the ecliptic *ie* to the plane of the earth's orbit.

(4) The longitude of the ascending node ( $\Omega$ ) *ie* the direction at the sun of the point on the orbit (measured from the vernal equinox or first point of Aries) at which the planet crosses the ecliptic from its south to its north side. This defines the *aspect* of the orbit.

(5) The longitude of the perihelion ( $\omega$ ). This defines the direction of the major axis in the plane of the orbit.

(6) The period ( $P$ ) *ie* time the planet takes for a revolution.

(7) The longitude of the planet at the epoch ( $L$ ) or time ( $T$ ) of the planet's perihelion passage. These elements are given for the several planets in Table I.

Since the orbits of Mercury and Venus lie within that of the earth these two planets when observed telescopically will show phases similar to those presented by the moon. When on the far side of the sun *ie* near the time of superior conjunction each of them will appear like a small full moon. As the angle earth-planet-sun increases a proportionally diminishing fraction of the illuminated surface will be presented to view and when the angle reaches 90° the planet will appear half illuminated like the moon at first quarter. Following this a crescent form of steadily diminishing breadth will be assumed as the planet moves toward inferior conjunction at which point it passes between the earth and the sun. Subsequently to this the phases described will be repeated in the reverse order up to superior conjunction when the planet will again be full. The phases of a planet revolving outside the earth's orbit differ from those of Mercury and Venus in as much as the angle earth-planet-sun can never increase to 90°. Thus Mars although at times presenting a markedly gibbous aspect like a nine or ten days old moon is always more than half illuminated. In the case of Jupiter the defect of illumination is so small as to be almost imperceptible but during the occultation of a satellite the planet's dark limb is seen across the satellite's disk, and a narrow black space separates the latter from the bright part of the planet's surface. In the cases of the planets revolving outside Jupiter the phase is quite imperceptible even in powerful telescopes. The variations in apparent diameter and brightness will

of course also be small in the cases of the remoter planets.

**Physical Condition and Atmospheres.**—There is a broad distinction between the two groups of the major planets on either side of the zone of the asteroids. The planets of the inner group are of relatively small mass and high density and possess solid surfaces. Those of the outer group, especially Jupiter and Saturn, are of much larger mass but of very low density. The density of Saturn is actually less than that of water. The masses of the planets possessing satellites are derived from the distances and periodic times of the satellites by an application of Kepler's third law. The masses of Mercury and Venus are deduced from their gravitational effect on other bodies.

There is for each of the planets a certain critical velocity determined by the force of gravity at its surface and a particle of matter travelling at a speed in excess of this value will escape from the planet in question and revolve in an independent orbit round the sun. These critical values for the several planets are given in column 12 of Table II. Now according to the kinetic theory of gases every molecule of a gas is an independent particle and is in constant motion. Its velocity will depend on the atomic weight and the temperature and may attain to thousands of feet per second. A molecule with such a high speed in the upper part of a planet's atmosphere where it will be comparatively free from collision with other molecules cannot be retained by a body with low surface gravity but will escape into space. It might be expected accordingly that only the large and massive planets are enveloped in dense atmospheres and that those of small mass and low surface gravity have atmospheres which are of greater rarity and tenuity. Observation shows that this is in general the case. The spectra of the planets of the outer group contain strongly marked absorption bands due to their atmospheres while those of the inner group—Mars, Venus and Mercury—show but little deviation from the ordinary solar spectrum. It may be that the light received from Venus is almost entirely reflected from the upper part of the atmosphere but in the cases of Mars and Mercury most of it has passed through the planetary atmosphere twice. As a matter of fact the atmosphere of Mercury seems to be almost negligible. It is known that the moon which is still smaller has none at all that is appreciable and it cannot be supposed that an atmosphere exists on any of the minor planets the largest of which (Ceres) has a mass only  $\frac{1}{8,000}$  and a surface gravity only  $\frac{1}{30}$  as great as the corresponding values for the earth.

The interpretation of the spectra of the outer planets apart from the mere fact of considerable absorption is puzzling. From the accompanying plate and Table III it will be seen that there are one or two rather faint but broad bands in the spectrum of Jupiter which are seen to be much stronger in the spectra of Saturn, Uranus and Neptune. The two latter also contain a

number of additional bands. The origin of the bands was still unknown in 1917.

**Temperatures of the Planets.**—A matter of special interest in regard to the planets is that of the temperature of their surfaces. Speaking generally it may be said that the surface temperature of a planet which is without appreciable heat of its own and is warmed only by the solar radiation is determined by a number of factors of which the following may be specially mentioned—(1) The distance of the planet from the sun the intensity of solar radiation obeying the well known inverse square law. (2) The degree in which the planet's surface approaches that of a perfect radiator. (3) The presence or absence of an atmosphere and the nature of such atmosphere. (4) The planet's rotation. It can be shown that a black sphere without an atmosphere rotating with sufficient rapidity to be heated equally all round would have a mean surface temperature given by the formula  $T = 77 / \sqrt{R}$  where  $T$  is the temperature in degrees centigrade reckoned from the absolute zero and  $R$  is the distance of the body from the sun.

taking the earth's distance from the sun as unity. But should the periods of axial rotation and orbital revolution be equal so that the body turns always the same face to the sun the formula becomes for the point immediately under the sun  $T = 392 / \sqrt{R}$ . This means e.g. that on a perfectly radiating planet without an atmosphere at the distance of Mercury the point on the surface where the sun is overhead would have a temperature of 631° C (absolute). With a quick rotation the mean surface temperature would be about 445° C (absolute) or 342° F. The corresponding absolute temperatures at the distance of Mars come out 318° C

(115 F) and 4 C (-5 F) and at that of Neptune only 71 C (-55 F) and 51 C (-65 F). The actual temperatures will of course be affected to a large extent by the presence of an atmosphere which while directly reflecting a large proportion of the solar rays checks the escape by radiation of such as penetrate it and reach the planet's surface.

Until comparatively lately however the only available methods of estimating the surface temperatures of the planets were those based on general physical principles and in view of the great uncertainty as to the conditions prevailing on the planets and particularly as regards the nature of their atmospheres the conclusions arrived at were necessarily of a highly speculative character. But in recent years great strides have been made in the development of radiometric apparatus and by the use of thermo couples in vacuum cells with extremely small receivers and sensitive galvanometers it has been found practicable to measure with considerable accuracy the radiations received from the planetary surfaces and even in some cases from particular parts of those surfaces. In these measurements transmission screens of such materials as water quartz glass fluorite are interposed in the path of the ray which absorb the radiations in certain parts of the spectrum and thus enable the total radiation to be resolved into a number of spectral components. For example when a water cell is employed the infra red heat radiations are cut out and the ratio of the transmitted to the total radiation of the planet provides data for determining the temperature of the planet's surface. It will be clear that if the ratio of transmission through the water cell is large the heat radiated by the planet is small but that if the transmission ratio is small the proportion of heat rays is comparatively great. The matter is of course complicated somewhat by the presence of water vapour in the terrestrial and planetary atmospheres but the necessary corrections can be estimated and it is found that the reduction of the observations by various methods such as those based on (1) the distribution of energy in the spectrum (2) the fourth power law and the measured water cell transmission as worked out by Menzel and (3) a comparison with observations of the moon all lead to satisfactorily accordant results.

The conclusions reached are of great interest. Measurements of the heat radiations from Mercury give values which support the conclusion that the planet's periods of rotation and orbital revolution are the same and that its atmosphere is negligible or nearly so. In the case of Venus a considerable amount of heat is apparently emitted even by the unilluminated surface which suggests a quick rotation. Observations of Mars at the Lowell observatory in 1922 1924 and 1926 which are in fair agreement with those made at Mount Wilson show that despite the planet's distance from the sun the temperature during the day rises well above the freezing point and exceeds that value even at the polar regions during the summer that the bright regions are cooler than the dark regions that the summer hemisphere is warmer than the winter hemisphere that afternoon temperatures are higher than those of the morning and that low temperatures are recorded from what appear to be cloud surfaces which check the escape of heat from below. These radiometric results for Mars are consistent with telescopic observations of the surface features—particularly with the melting of the polar caps—and with terrestrial experiences of seasonal and diurnal temperature changes.

As regards Jupiter and Saturn the results obtained have given occasion for some surprise. Physical observations of the surface features of these planets particularly the former combined with the known low density suggest very strong analogies with the sun and apparently give evidence of considerable stores of heat. Yet the radiometric researches of Coblenz Lampland and Menzel indicate a temperature of about 100 C for the visible surface of Jupiter and a value slightly higher for that of Saturn. Dr H. Jeffreys too, has concluded on theoretical grounds that the temperature of these planets is low. Observers however, find it difficult to accept the position that the very large and violent disturbances and rapid changes exhibited by Jupiter can have their origin merely in solar radiation, and incline to the view that whatever the superficial temperature there must be a considerable dif-

ference between that at the centre and that of the external parts of the planets' mass. The difficulty might be removed if it can be supposed that the cloudy surfaces of Jupiter and Saturn are composed of substances which have a very low boiling point.

**Habitability of the Planets**—I will be clear that the various points above referred to have an important bearing on the question of the suitability of the planets to be the abode of life. Apart from the question of temperature their low density rules out the large planets of the outer group as possible habitations for anything at all resembling human life. It is on the planets of the inner group with their solid surfaces and their proximity to the sun that the requisite conditions must be looked for. Of these planets Mercury whose periods of axial rotation and orbital revolution are identical with its scanty atmosphere its extremely high temperature on the sunlit side and the intense cold of that which is in perpetual night cannot be habitable unless it be in the restricted region near the boundary of the light and dark hemispheres. Of Venus almost nothing is known apart from its resemblance to the earth in volume and mass and its possession of a seemingly cloud laden atmosphere. About Mars much information has been gathered. Its transparent atmosphere has permitted a study in considerable detail of its surface markings and physical condition with the result that the planet is known despite its small dimensions to exhibit important resemblances to the earth. It may accordingly well support some form of animate life though certain important differences in the conditions prevailing on its surface would seem to preclude its habitation by beings quite like man. More than this can hardly be said. But it may be held probable that on a planet where the required conditions are found life of some sort exists and that at some period in such a planet's life evolutionary processes may bring its inhabitants to the status of intelligent beings.

See ASTRONOMY and articles under planetary names.

**PLANETARIUM** is the name given to an arrangement made by Zeiss of Jena for producing an artificial sky. By optical methods images of the sun moon planets and stars are projected on a large hemispherical dome and by mechanical and electrical means the apparatus can be revolved so as to show the principal motions. The name planetarium is apparently given because of the success with which the apparent motions of the planets amongst the stars can be shown but the apparatus makes possible the representation of many other astronomical phenomena.

For several centuries orreries have been used to demonstrate the motion of the planets round the sun according to the Copernican system. Perhaps the best arrangement of this kind is in the German Museum at Munich where the observer can be carried in a cage which is moved in a path representing the earth's orbit. By means of a periscope he can look out on the motions of the other planets and at the stars of the zodiacal constellations shown on the wall by means of small electric bulbs. But it is impossible in a model of this nature to make the relative distances correct and thus to get the proper alignment of the various bodies. When this instrument was ordered from Zeiss in 1913 it was suggested that another astronomical model might be made depicting the heavens as actually seen from the earth and it was suggested that the heavenly bodies might be represented by electric bulbs fixed or moving on a rotating dome. This suggestion however was soon discarded in favour of another due to Dr Bauersfeld in which the images of the bodies were projected optically on a fixed dome. The resulting apparatus has been a great success. It is found that when a dome 50 ft or more in diameter is used the appearance is extremely like that of the actual sky. For the stars it is merely necessary to have the projector mounted so that it can be rotated about an axis parallel to the earth's axis. For the sun moon and planets small models true to nature, are constructed. The angles between the orbit planes are allowed for and by the use of eccentric circular motion the elliptic motion is quite closely represented. For showing say the planet Venus the model has pins representing Venus and the earth moving round the sun. A little projector is attached to the pin representing Venus and a linkage between the planets always directs the light away from the earth. Consequently, the image of the planet on the dome

# PLANETARIUM

ADLER PLANETARIUM AND ASTRONOMICAL MUSEUM AT CHICAGO  
THE GIFT OF MAX ADLER

1 Interior showing project of Max Adler  
henceforth known as the Adler Planetarium

2 Exterior view of the Adler Planetarium  
3 Interior view of the Adler Planetarium showing the large audience seated in the hall

is in the correct position among the stars. The gearing is so arranged that the mean motion is accurately represented and only comparatively slight periodic effect affects the positions of the sun, moon and planets. The phase of the moon is shown by an occulting device.

The planetarium can be operated at various speeds corresponding to the phenomenon to be demonstrated so that even such a slow motion as that of the procession of the equinox is within its range. To show the rising and setting of the heavenly bodies a day is compressed into an interval of from 1 to 4 minutes, so that of the planets the diurnal motion can be put out of gear and a year run off in intervals varying from seconds to 4 minutes. The original model was made for one latitude only but in later ones by introducing an additional axis of rotation the latitude can be altered at will. The stars are shown brighter than they appear in the sky—the eyes of the spectators coming from the daylight would otherwise take too long to be sensitive enough to see them. It is of course impossible to make the sun as bright as in nature but this has the advantage of enabling the stars to be seen in the sky along with the sun and thus demonstrate the motion of the sun amongst the stars.

With the planetarium the spectator can see in an hour or so motions which can only be seen in the heavens by years of watching. When a year is compressed into a minute or two the planets can be seen chasing one another about the sky describing loops advancing and retrograding just as they do so slowly in nature. Great attention has been paid to details so as to make the apparatus as perfect as possible. e.g. the brightness of the objects is dimmed as they approach the horizon and the light is practically cut off as the star actually reaches the horizon. The date corresponding to the configuration can be projected on the dome as well as the names of the constellations and by means of a luminous pointer a lecturer can point out objects of interest. Planetaria have for some time engaged popular interest in a number of German towns. In the United States the first to be erected was the Adler Planetarium at Chicago but others are now to be found in Los Angeles, Philadelphia and New York, the last named of which was opened in 1935.

(J. J. N.)

**PLANING-MACHINES** rank in importance with the lathes and drilling machines and cut various kinds of plane surfaces in metal. The principle is that of attaching the metal to a long table which slides truly upon a massive bed so that by holding a cutting tool in a slide overhead the material becomes shaved off as the table moves. The width of surface is treated by giving the tool a cross traverse. The slide moves on a horizontal rail for this purpose and the rail is adjustable up and down two uprights flanking the bed. Tool slides are often put on the faces of the uprights as well so that the sides of the work may be planed. Planing machines are of value both for big and small articles; they may take one of the former and deal with it singly or a whole string of small objects can be clamped in line on the table and surfaced off. (See also WOODWORKING MACHINERY MACHINE TOOLS)

**PLANKTON** is the name which is now given to the drifting (and usually microscopic) life contained in the waters of the seas, lakes, ponds and streams. Its study was begun just prior to 1845 by the great German zoologist Johannes Müller in the sea round Heligoland. Associated with Müller in 1845 were his pupils Max Müller, Busch, Wilms, Wagener and others. Ernst Haeckel as a student of 20 years of age was with J. Müller at Heligoland in 1854 and began to study the plankton. When said Müller "you have once entered this pelagic magic world you will not easily leave it again." Rapid extension of plankton investigation followed both in Germany and in Great Britain and the great names associated with this branch of 19th century marine biology are Heinrich Müller, A. Kolliker, C. Gegenbaur, Leuckart, Carl Vogt, T. H. Huxley and McIntosh.

In 1873-76 the 'Challenger' made her voyage of circumnavigation and great collections of plankton were made in all the seas of the world. Many other voyages have since been made but there

has been no other of much war was carried out during the first few years under the direction of V. V. S. Thomson and John Murray. Another equally great mark is the Plankton Expedition carried out by the 'National Vector' Huxley on the 'Albatross' and with him were a certain Brant Schütt, F. C. K. K. K. All the great work on the plankton has been continued by the 'National Vector' Huxley and by the extraordinary fertility of Huxley and the methods with their results make up the modern science of Hydrobiology.

**The Plankton in General.**—The planktonic pelagic life of the sea and of fresh waters consists of microscopic organisms. There are some large plants and animals that are planktonic in their habits such as the giant weed (*Sargassum*), medusae, siphonophores and other jellyfishes, some molluscs like the pteropods (whale food), the pearly nautilus, etc. It is no usual however to consider these relatively large plants and animals when we are discussing the plankton; in practice we take the latter to mean the organisms which are as a rule invisible to the naked eye because of their minute size and transparency. Even the most transparent water may contain very large numbers of these microscopic organisms and sometimes they are so abundant that the water may be coloured or turbid and they may even tint snow and ice. A practical distinction is made between the Macroplankton which can be caught by filtering the water through very finely woven silk cloth and the Microplankton which are so small that they escape through the pores of the finest fabrics that can be employed. Later on we shall consider more fully the methods of collecting the plankton. A further practical distinction in discussing distribution is that between the Transitory Plankton and the Permanent Plankton. The former category includes all those organisms which have a brief pelagic drifting stage in their life history after which they develop into actively swimming large animals (the Nekton) or into rooted or sedentary plants and animals (the Benthos). The latter category includes a multitude of species of organisms which live throughout their lives as planktonic passively drifting individuals. It is customary to distinguish between Oceanic and Neritic Plankton, the former inhabiting water which is far from land and the latter being practically restricted to the zone of shallow water near the Continental coasts. Then there are many plankton organisms that prefer to live near the surface of the sea and these we call the Epipelagic while there are others that habitually live in the deeper layers of the ocean; these make up the Bathypelagic. Finally the different oceans, seas, zones of latitudes, etc. tend to harbour characteristic plankton communities so that a naturalist who is very familiar with plankton investigations can often say where an unknown sample has been collected.

After this general survey we may now consider the various kinds of organisms that occur in the plankton.

**The Transitory Plankton.**—A great number of marine organisms 'spawn' in the general sense—that is they discharge their spores, eggs and larvae into the sea where these things simply drift about while they undergo development. After the latter process is complete the organisms leave the plankton communities either to settle down on the sea bottom or to roam about in the sea as freely locomotory animals. Thus the eggs and larvae of innumerable marine species are transitorily planktonic organisms; finally becoming benthic or nektonic ones. Benthos includes all the organisms that live on or are attached to the sea bottom while nekton includes those others that are actively locomotory in their habits. (See MARINE BIOLOGY)

Thus most of the fishes spawn emitting their eggs and spermatozoa into the sea water where the processes of fertilization and embryonic development occur. When embryonic development ends the little fish is a larva and as such it simply drifts about in the sea. Finally its development is completed by a metamorphosis and then it assumes the form and habits which are characteristic of its species. It leaves the plankton and becomes a nektonic animal. Most of the marine Crustacea reproduce in the same way, that is they may directly emit eggs into the sea.

FIG 1—PLANKTON DIATOMS PERIDINIANS ALGAE (HIGHLY MAGNIFIED)

or the parents may for a time carry these eggs attached to their bodies but in most cases the embryos develop into larvae which are always small practically non migratory and which finish their development while drifting in the plankton. Many of the Mollusca lay their eggs (enclosed in cases or cocoons) on the sea bottom but others emit the eggs and sperms into the water. In all cases however the larvae drift about for a time. Just the same general life history is displayed by most of the worms, the polyzoa and practically all the echinoderms, sponges and coelenterates. The rooted algae liberate their zoospores into the sea on the littoral and shallow water zones and there these myriads of (even microscopically) tiny organisms drift about and perish.

The wealth of life that is so produced is incredibly great. Even one large cod will spawn annually several millions of eggs all of which exist for a short time in the plankton and some of which become larvae and small baby cod. So also with almost every kind of marine animal its eggs that are spawned every year must generally be counted by the thousands or hundreds of thousands. Yet on the average of all the eggs produced by any marine animal only one or two can undergo development and growth up to full reproductive maturity. The remainder destined to perish in the struggle for existence have their life phase for a few weeks or months in the hordes of transitorily planktonic organisms.

**The Permanent Plankton.**—In all parts of the seas and oceans the plankton always contains great numbers of organisms that have this habitat throughout their whole lives. There are many large permanently planktonic organisms—some algae, many medusae (which are sometimes so numerous as to make a visible coloured carpet on the surface of the sea), many other coelenterates (such as the Siphonophores and the Ctenophores), some worms, some molluscs like the pearly nautilus and the Heteropods and Pteropods (the latter may exist in great shoals and form the food of the whalebone whales). These large plankton animals and plants are however few and unimportant when compared with the multitudes of the microscopically small animals and plants which abound even in water that appears to

the naked eye to be perfectly clear and barren.

Among the Crustacea the little animals called Copepods, Schizopods, Ostracods, Cumacea with some less abundant groups are always and everywhere present in the plankton and some times they are extraordinarily abundant. They live mainly in the upper layers of the sea but many species are also found in very deep water. Their significance even for human affairs is very great for they are the food of such fishes as herrings, pilchards, sprats, hake and other kinds that are regularly caught by the fishermen. Many other marine animals of course eat them. They may be so very abundant that sufficiently large numbers to cook and eat may be taken by fine nets drawn through the sea.

Worms belonging to the groups called Polychaetes and Chaetognaths (these are the bristly jointed worms and the translucent arrow worms) abound. The only planktonic vertebrate (or rather chordate) animals are some of the Tunicates and one kind of these creatures—the salps—may at times be so very abundant in the sea as to clog and sink the drift nets set by the herring fishermen. The Heteropods and Pteropods are the only permanent plankton dwellers belonging to the Mollusca. There are no Echinoderms that are always planktonic but the beautiful larvae of these animals live for a time pelagically. The Coelenterates are some of them permanently planktonic (see above) but most of them (the zoophytes, sea anemones, corals, etc.) live on the sea bottom and their larvae appear for a short time only among the plankton. None of the sponges are permanent plankton denizens.

Great numbers of species of unicellular animals and plants are always planktonic. We shall notice the principal kinds very briefly, premising that their full description means writing great books on zoology and botany. Among the Protozoa are the Foraminifera and Radiolaria—the former characterized by their calcareous and the latter by their siliceous skeletons. These animals are microscopic in size (though sometimes big enough just to be discerned by the naked eye). They are found everywhere in the sea and they are so numerous that extensive regions of ocean floor at depths of about 2 to 3 m. are covered with fine oozes made up almost entirely of the shells of Foraminifera and Radiolaria that

FIG 2—VARIOUS LARVAE OF MARINE ANIMALS (HIGHLY MAGNIFIED)

live and die in the upper layers of the ocean. These shells are beautiful and interesting objects when seen under the microscope. Very important from the human point of view are the Peridini-ans. These are unicellular organisms that can be regarded either as plants or animals and they are about as abundant as the Protozoa that we have already mentioned. They also have very elegant shells made of a kind of cellulose material which is impregnated with silica. Great numbers of Peridini-ans live in the sand and mud in the very shallow sea bottom near the land, but most of the species are pelagic—that is, they are permanently planktonic. The pelagic Peridini-ans are important food materials for some fishes—mainly the pilchard (when it is in the sardine stage). These organisms are interesting from another aspect—it is they that mainly cause the phosphorescence of the sea. Sometimes when the sea is very fiery, an organism called *Noctiluca* is so abundant that the water may be visibly turbid and discoloured.

The Diatoms are to be regarded as unicellular algal plants and they are on the whole the most abundant of all the planktonic organisms. They have external transparent, siliceous shells which are elegant in form and are often sculptured with beautiful patterns. They exist everywhere in water—in ponds, lakes, on the mud and sand of the foreshore and sea bottom, attached to weeds, etc.—the main restriction on their presence is the absence of light for being green plants they cannot live except in the presence of solar radiation. There are innumerable species and they are so abundant in the ocean that millions of square miles of bottom at about 1000 fathoms in depth (and mainly in the Antarctic) are covered by the dead shells of Diatoms.

**The Microplankton**—The above observations apply to the larger planktonic organisms, but there are numerous species which are not captured by using the ordinary tow nets (presently we refer to the methods that are employed by the planktologists). These smaller species (the Micro or Nannoplankton) include many minute Diatoms, Peridini-ans, shelled and naked Protozoa, Flagellates, unicellular Algae and algal zoospores. There are of course hosts of marine bacteria, but these we do not consider in this connection. We shall see that in point of numbers of individuals the microplanktonic organisms far exceed the larger forms.

**The Seasonal Variations in the Plankton**—Everywhere in the sea and in fresh waters the composition and abundance of the plankton change with the season. To some extent the nature

and sequences of these changes depend on the region which is being investigated and this is particularly the case when we consider the larvae for the nature and abundance of these will depend on the nature of the local benthic and nektic faunas. If however we consider the North Atlantic region the following general descriptions will apply to some extent at all events to most local regions.

The cold and dark months, December to February, are generally periods when the marine plankton is scarce and when the Diatoms and Peridini-ans in particular are relatively few in number. This is because of the feeble intensity of sunlight which is necessary for the growth and reproduction of these organisms. But some time about March or April there is a great outburst of life in the sea. Certain indispensable food materials (inorganic nitrogen compounds, silica and phosphates) have been accumulating during the dark months; in the spring there is a rise in sea temperature and this acts as a stimulus to vital processes, but the main factor is the increase in the length of the day and the growing intensity of sunlight. The result of these changes is that all the vegetable plankton, but particularly the Diatoms, become stimulated to reproduce so that there is almost an explosive outburst of life in the sea and great swarms of Diatoms invade the shallow sea areas. This is the great event of the year—the vernal maximum of vegetable life in the sea.

Immediately following it comes the reproduction of the nektic and benthic animals. Hosts of fishes, Crustacea, Mollusca, Echinoderms and worms spawn their eggs into the water or deposit them on the sea bottom. The eggs hatch out and the waters of the sea teem with larvae. The latter must feed and they utilize the vegetable plankton (Diatoms, algal spores, etc.). The production of animal larvae lasts into the early summer (or even later with some species), but while it goes on there is a diminution in the abundance of the Diatoms. Those indispensable food stuffs which accumulated during the winter months are largely used up while the vernal maximum of vegetable plankton lasts. The extraordinary abundance of Diatoms therefore falls off during the months of June to August, but about then the Peridini-ans begin to increase. The summer months are characterized then by a relative scarcity of Diatoms, a great increase in the Peridini-ans, an abundance of larvae belonging to many groups of invertebrates and a great abundance in the Copepods.

In the autumn or early winter the Diatoms sometimes increase

again—there is an autumnal maximum. But this is very brief phase and with the shortening of the day and the drop in sea temperature towards the annual minimum all kinds of planktonic life in the sea decrease. In this very summary account of the seasonal change stress has been laid on certain physical agencies—light, temperature and inorganic food substance—that are regarded as of importance, but we must never forget that intrinsic causes are also operative. Heredity has implanted in the organizations of all marine organisms a cyclical tendency so that the annual outbursts of reproductive activity are stimulated or set off so to speak by the seasonal change.

**The Abundance of the Plankton.**—There is no part of the seas and oceans where planktonic organisms do not occur. Even in the greatest depths of the ocean we suspect that certain microcrustacea exist. Under the ice in polar regions rich collections may be taken and there are abundant algal organisms in the pools that form in hollows on the surfaces of ice floes in the summer. Snow and ice may actually be tinted with diatoms and other organisms. The richest plankton in any part of the world ocean is that found just on the borders of the polar seas in the regions of melting ice. In general the temperate and cold seas are rich in plankton while the tropical and warm waters are relatively poor.

What absolute quantities of plankton organisms exist in the sea? There is so much variation with regions and seasons that it is difficult to give definite figures without going into great detail. A long series of experimental hauls made in the Irish sea gave a general average of one or two organisms in every cubic centimetre of water while at the periods of greatest abundance each cubic centimetre contained about a dozen organisms. But this included only the larger planktonic individuals and it is generally the case that the micro forms are far more numerous. In some experiments made at Plymouth it was shown that there must have been at least several hundreds of individual organisms (macro and micro species) in every cubic centimetre of sea water.

These estimates refer to the numbers of organisms in the sea water at a particular moment and we ought also to consider the rate at which they reproduce and grow. There is not the knowledge at present which would enable us to make such estimates but some approximate idea of the total mass of living material that is produced in a sea area can be obtained by indirect methods. We must note first that all animal life in the sea depends on vegetable life; the animals can only subsist by eating other animals or plants but the plants can use as their source of food stuff the carbonic acid that is dissolved in the water. Utilizing the energy of sunlight they can synthesize this carbonic acid into cellulose and other vegetable substance. Now it is mainly the diatoms, peridiniums (and other plankton organisms that have the vegetable mode of nutrition) that do this for the total mass of all the rooted algae must be very small in comparison with the mass of the vegetable plankton. It is possible by routine chemical methods to find out how much carbonic acid is removed from solution in a sea area during the spring and summer seasons and then converted into carbohydrate by the activity of the vegetable plankton. The result is very surprising: at least 300,000 kilograms of dry organic carbohydrate must be produced during a single season per square kilometre of sea surface. Or expressed in more familiar terms a spring and summer of organic production in the sea gives origin to about ten tons of moist vegetable substance per acre of sea. This is the marine harvest due to the activity of the vegetable plankton; at present man reaps only a very small fraction of it in the shape of the fishes and other edible animals that he catches.

**Methods of Studying Plankton.**—A veritable wonderland awaits the amateur naturalist who can spend a short time at the seaside during the spring months. He will require a student's microscope (magnifying 50 to 500 diameters) and some cheap home-made apparatus. The net is simply a conical bag of the finest and strongest muslin obtainable; it is about 1 to 2 ft in diameter and about 4 ft long. Its mouth consists of an iron ring, to which a selvage of strong canvas is laced. The net is sewn on to this canvas edging. It is towed in the sea behind a rowing

boat for about half an hour.

When the net is hauled it is drained of water and turned out side in. The pointed end is then rinsed in sea water contained in a 1 lb glass jam jar. A small sieve is made by loosely tacking a piece of mu lin on a square wooden frame about 4 in along each side. The water containing the catch is then slowly poured through the central part of the sieve. Then the latter is turned upside down and the plankton is washed off into a little sea water in the bottom of a saucer. This will now be a thick greenish turbid mass. A dipping tube is made (like a fountain pen filler but with a wider opening) and some of the plankton is lifted with this and put into a watch glass which is then examined under the microscope. Examined day by day the spring and summer plankton is full of the most beautiful things.

Nets contrived to fish quantitatively are also used. In such investigations fine miller's silk bolting cloth is used. This has meshes of over 100 to the inch. Heaps of organisms escape through this net. To catch the very minute plankton the water must be centrifuged or cultures are made in an analogous way to those employed by bacteriologists. Elaborate methods have been evolved for counting the organisms taken in a plankton catch.

**BIBLIOGRAPHY.**—There is a huge literature on plankton but many general papers are cited and their source stated in *The Marine Plankton* by Johnstone Scott and Chadwick (Liverpool 1924).

**PLANTAGENET**, a surname conveniently but unhistorically applied to the royal line descended from the union of Geoffrey count of Anjou with the empress Maud who are now styled by historians the Angevin house. It was historically only a personal nickname of Geoffrey as was Curtmantel of his son (Henry II) and was derived from his wearing in his cap a sprig of the broom (*genet*) plant. When the fashion of personal nicknames passed away the members of the royal house were usually named from their birthplace as Thomas of Brotherton, Thomas of Woodstock and so forth. But Edward I and his younger brother the founder of the house of Lancaster had still nicknames respectively as Longshanks and Crouchback. In the later days of the dynasty the surname of Beaufort was adopted by the legitimated issue of John of Gaunt by Katherine Swynford but that of Plantagenet was bestowed on Arthur natural son of Edward IV who was created Viscount Lisle. It appears however to have been adopted as a surname by Richard duke of York (father of Edward IV) some 10 years before his death.

At the death of Geoffrey's grandson Richard I his younger brother John succeeded. John's younger son Richard king of the Romans left a son Edmund earl of Cornwall with whom his line ended; his elder son Henry III left two sons of whom the younger was created earl of Lancaster and was grandfather of Henry earl of Lancaster whose heiress married John of Gaunt (i.e. Ghent). (See LANCASTER HOUSE OF) John of Gaunt's next brother Edmund of Langley founded the Yorkist line. (See YORK HOUSE OF)

Although no other dynasty has reigned so long over England since the Norman Conquest the whole legitimate male issue of Count Geoffrey Plantagenet is clearly proved to have become extinct in 1499. See Genealogical Tables Vol 8 p 8.

**PLANTAGINACEAE**, a family of dicotyledonous herbs the best known members of which are the plantains (*Plantago*) cosmopolitan weeds of which five species occur in Great Britain and upwards of 30 in the United States. (See PLANTAIN) The family contains three genera and about 200 species. The seeds of *Plantago Psyllium* (Mediterranean) are used in silk and cotton manufacture. The flowers usually hermaphrodite and inconspicuous are wind pollinated.

**PLANTAIN**, a name given to certain plants with broad leaves. This is the case with certain species of *Plantago* *Alexandra* and *Musa* to all of which the term is popularly applied. The species of *Plantago* (family Plantaginaceae) are mostly weeds with a dense tuft of radical leaves and scapes bearing terminal spikes of small flowers; the long spikes of *P. major*, when in seed, are used for feeding cage-birds. *P. lanceolata* so called from its nat-

Something of romance attaches to the introduction into Argentina of a wheat from the Szechwan province of China. It has proved highly resistant to *Puccinia triticina* the rust which more than anything else threatened to suppress the great promise of wheat growing in South America. The introducer Mr W O Backhouse has now raised hybrids which both rust resistant and generally superior are fast becoming the standard forms.

From the Swedish station S alof have come a number of new wheats by crosses and peas. Swedish Iron wheat has added to its list by being a hold in Great Britain millers how ever dist the thick skin and the quality of its grain. The Little Joss and eoman wheats bred by Prof Sir R H Bifen and introduced, 1912 and 1917, occupy one tenth and one fifth respectively the whole wheat area of the 14 principal producing counties. Little Joss a hybrid from Ghirka (Russian) and Square Head Master (British) are the only forms with a definite resistance to yellow rust (*Puccinia glumarum*) besides possessing a marvellous standing capacity and a curiously wide soil adaptation. Yeonan is also a product of premeditated synthetic breeding. The parents were Browick (British) and Red Life—the best bread making wheat. Heavy yield and great standing power are merits it shares with the best of the older forms but its quality or bread making capacity has set a standard formerly believed impossible in British wheats.

**Barley**—Barley is of peculiar interest because the quality of beer making kinds is nearly as important as the yield. At the end of the 19th century Cevalier and Standwell were the prevailing forms in Ireland. Archer barley was introduced from England in 1900 and Irish Archer a selection made by Dr H Hunter soon displaced the older varieties. An even more marked success attended his hybrid Spratt Archer (derived from a cross between Archer and Spratt the latter being an old form with special adaptation to peaty soils) distinguished by high yield exceptional standing power and superior quality it now occupies almost 90% of the barley area of Ireland. It is estimated that £40 000 spent on breeding and testing in Ireland during the period 1905–25 has brought an increase equivalent to £250 000 per annum. Contemporaneously the selections Archer and Plumage introduced by Dr E S Beaven of Warrminster have contributed to the prosperity of English growers.

**Roots**—Roots such as potatoes which flower uncertainly and mangolds whose varieties freely intercross in the field are difficult subjects. But mangolds and swedes have yielded to that systematic patience which has done so much in Danish agriculture. Helweg in Denmark first made clear that the only sound basis of estimation for mangolds was yield of solid matter per acre and not mere wet bulk. Next he demonstrated that different forms or strains within any one variety might be widely divergent in gross yield and percentage of solid matter. Indeed two strains of the same variety might correspond to a difference of £6 to £8 in value of feeding material from one acre. The best strains were picked out and by persistent teaching all bad strains were forced out of cultivation. Good seed was ensured and roots came to have a greater feeding value per acre than corn. In Denmark the area under roots has steadily grown and when the World War stopped the importation of feeding stuffs it was roots that saved Denmark. There was a time when wart disease (*Synchytrium endobioticum*) appeared to threaten wholesale destruction of British potato crops. But steady production of immune varieties reinforced by appropriate legislation may now be said to have brought security to the one great crop in which this country is self supporting.

**Other Staple Crops**—Rice in Malaya and South India the millets in India the Fulghum oat of Texas and Kansas the hybrid round tipped tobacco of Connecticut Svalof's Victory oat which has proved itself to be one of the best oats grown in Great Britain and Dr C A Barber's new sugar canes in India are among many other valuable new products of the last decade.

**PLANTIN, RISTOPHE** (1514–1589) French printer was born in a village near Tours (probably Saint Avertin). He learned bookbinding and bookselling at Caen and having married in that town settled in 1549 as bookbinder in Antwerp where he was soon known he first in his profession. A bad wound in his arm seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was *La Institutione di una fanciulla nata nobilmente* by J Bruto with a French translation and this was soon followed by many other works in French and Latin which in point of edition rivalled the best printing of his time while the masters of the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562 Plantin himself being absent Paris his workmen printed an heretical pamphlet which caused his movables to be seized and sold. It seems however that he recovered a great deal of the money and in 1563 he associated himself with some friends to carry on his business on a large scale. Among them were two grand nephews of Dan Børg who furnished him with the fine Hebrew types of the renowned Venetian printer. His editions of the Bible in Hebrew Latin and Dutch his *Corpus juris* Latin and Greek classics many other works produced at this period are renowned for their beautiful execution and accuracy.

A much greater enterprise was planned by him in those years—the publication of a *Bibliotheca polyglotta* which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II king of Spain who sent him the learned Benedictus Arias Montanus to superintend the work. It was finished in five years (1569–73 8 vols folio). Plantin earned little profit but received the privilege of printing all liturgical books for the states of King Philip and the office of prototypographus regius. Though outwardly a faithful son of the church he was till his death the partisan of a mystical sect of heretics and it is now proved that many of their books published without the name of a printer came from his presses to ether with the ssals breviaries etc for the Roman Catholic Church.

Besides the polyglot Bible Plantin published in those years editions of St Augustine and St Jerome the botanical works of Dodonaeus Clusius and Lilius the description of the Netherlands by Guicciardini etc. In 1575 his printing office reckoned more than 20 presses and 7 workmen besides a similar number that worked for the office at home. But in Nov 1576 the town was plundered and in part burnt by the Spaniards and Plantin had to pay an exorbitant ransom. He established a branch of his office in Paris and when in 1583 the states of Holland sought a typographer for the newly elected university at Leyden he left his much reduced business in Antwerp to his sons in law John Moerentorf (Moretus) and Francis van Ravenghien (Raphelengius) and settled there. When in 1585 Antwerp was taken by the prince of Parma and affairs became there more settled he left the office in Leyden to Raphelengius and returned to Antwerp where he worked till his death on July 1 1589. His son in law John Moretus and his descendants continued to print many works of note in officina Plantiniana but from the second half of the 17th century the house began to decline. It continued however in the possession of the Moretus family which religiously left everything in the office untouched and when in 1866 the town of Antwerp acquired the old buildings with all their contents for 1 200 000 francs the authorities created one of the most remarkable museums of its kind in existence the Musée Plantin opened Aug 19 1877.
